profession that in by far the largest number of cases pulmonary consumption begins in the apex of either lung. Under these circumstances one is naturally led to ask why the apex is so susceptible to, and the middle and lower portions of the lung enjoy such exemption from, the onset of this disease? This elective action of the malady is, as I shall endeavor to show, partly due to the shape of the chest and to the arrangement of the bronchial tubes, and partly the result of artificial influences to which the chest is exposed. These tubes are divided in such a way that they conduct the air chiefly in a downward direction toward the base of the lungs, hence, the lower part of the chest is filled first with air, and the apex last, or not at all, except during a deep inspiration. This partial filling is also due to another cause. Prof. Mosso has proven by experiment that we possess nearly one-fourth more breathing space in the lungs than is actually necessary to carry on the processes of life. This may be regarded as a very wise provision of nature to guard against certain exigencies of life, as when, for example, in pneumonia, capillary bronchitis, etc., a portion of lung tract is impaired, or when, as in ascending high mountains, larger air space is required on account of the attenuated condition of the atmosphere in such regions; but it is also very evident that under ordinary conditions of life near the sea level, this lavish supply of lung material becomes a source of great danger to its possessor. For if the air capacity of the lungs exactly equalled the oxygen demands of the body, it is quite obvious that the whole lung surface would be actively engaged in supplying air, and would, in consequence, be well inflated; but if three-fourths of the lung surface is able to perform the work of the whole, then one-fourth remains more or less idle; and this part is the apex, which, on account of the lack of exercise, in consequence of defective inflation, becomes weaker, while the active parts become stronger.

The truth of the matter, however, is that the extraordinary size of our lungs is not a wise provision of nature which protects us against the accidents of disease, etc., but it is due to the fact that as such they have been transmitted to us from our savage ancestors; who, in consequence of their active outdoor pursuits of hunting, fishing, etc., were compelled to have a larger lung surface to satisfy the greater air-hunger of their bodies than we do who follow the more quiet and sedentary callings of a higher civilization. The truth of this proposition is confirmed by the fact that during inactivity a man breathes 480 cubic inches of air per minute, and while walking at the rate of four miles per hour he breathes 2400 cubic inches, and if he walks at the rate of six miles an hour he takes in 3260 cubic inches of air per minute. The difference between 480 and 2400 cubic inches air capacity shows that during the exercise of walking even at the rate of four miles an hour, five times more lung surface is employed than during rest, showing conclusively that bodily activity enhances the expansibility not only of the apex, but also of the whole pulmonary surface.

Further proof that a lack of apex breathing is often responsible for the beginnings of consumption is found in the fact that the female is less liable to this disease than the male in civilized life. This I have shown from a large mass of statistics in a paper entitled Female Dress as a Determining Factor in Consumption, and which was published in the *Medical News* for January 7, 1888. It is well known that the female breathes chiefly with the upper portion of her lungs, that the male has but very little movement here, unless it is especially cultivated, and that he breathes principally with the lower part of his lungs. The former is known as the costal, and the latter as the abdominal type of breathing. This difference in breathing between the two sexes is undoubtedly acquired through the mechanical influence of clothing, and is not original; as may be judged from data[1] which I recently obtained from an examination of the chest movements of the Indian female. It was there found that the costal respiration is absent in the full-blooded Indian, and that she possesses a strongly marked abdominal type of breathing, similar to that of the civilized male. The female savage wears but very little, if any, tight clothing around her abdomen, and hence, does not interfere with the abdominal movements, while the civilized female is addicted to the use of stays and tight clothing, which by restricting the abdominal breathing, produce a compensatory motion in the apex of the lung and bring about that fulness in the upper part of the chest which is characteristic of the civilized female. Leaving out of consideration the fact that the female has more costal motion than the male, there is nothing whatever in her condition to account for her greater exemption from consumption. She has everything else against her in this respect. She has the smaller lung capacity, and is the weaker of the two sexes; she, for the most part, leads a sedentary and quiet life, and is engaged principally in indoor occupations, and is thus constantly exposed to causes which are known to give rise to the disease in the male, as is well attested by the statistics contained in the report of the Rhode Island Board of Health for 1884. Here is found the mortality rate from consumption, among the two sexes, as it occurred in a variety of occupations during a period of twenty-five years, which, when proportioned to the whole number of each sex employed in each occupation, give the following results: Male nurses 1 : 42, female nurses 1 : 100; male teachers 1 : 9, female teachers 1 : 29; male cigarmakers 1 : 13, female cigarmakers 1 : 51; male operatives 1 : 44, female operatives 1 : 76; tailors 1 : 11, tailoresses 1 : 31. Moreover, in estimating the factors which differentiate between the two sexes in this respect, we must not leave out of view the fact that while the female suspends nearly all her wearing apparel from the abdomen and hips, the male supports all his clothing from the shoulders, and by thus encasing the upper end of his chest he adds another influence which tends to diminish his apex motion and which increases his liability to consumption.

[1] An Experimental Inquiry into the Chest Movements of the Indian Female. *Therapeutic Gazette*, May, 1887.

From these facts it may be safely inferred that defective apex expansion is one of the most prolific predisposing causes of pulmonary consumption, and it is in a great measure due to it that our clerks, telegraph operators, tailors, shoemakers, etc., who habitually become stoop-shouldered and flat-chested, furnish such a large contingency to the army of consumptives. I think it may be laid down, as a rule, that all apex-consumptives suffer from imperfect apex expansion, although the reverse is not necessarily true. Such individuals are, however, in constant danger of falling victims to the disease, especially if their general vitality is depressed to a point from which it reacts with difficulty against incidental disturbances, like colds, malaria, and other diseases. Many consumptives trace their whole trouble directly to a cold, and although "having taken a cold" is an expression which enters more frequently into common parlance than any other, yet I do not know another term to which there is less meaning attached than to this. A cold, as I take it, is chiefly a shock to the nervous system, in the chilly stage of which the peripheral, visceral, and vasomotor nervous systems are markedly affected, the capillaries and blood-vessels contract, the blood pressure rises, the surface of the body is cold, although the thermometer registers an elevated temperature. So soon as the primary effects of the shock have passed off, there follows a relaxation or paralysis of the same nerves, the blood again comes to the surface, and sweating more or less profuse, or some other flux may occur, after which the body will return to its normal condition again, provided the bodily reaction is good. But if any part of the body is already weakened, the effects of the shock will be felt more keenly here than in any other area, and the strong tendency will be towards the establishment of permanent disease. In the lungs, under these circumstances the product of the nerve-shock manifests itself, as it does in all organs with mucous surfaces, in the form of a catarrh; which usually selects the apex, because, as we have seen, the nutrition-tone of this locality is already lowered by reason of its previous functional inactivity.

That catarrhal inflammation is a common sequence of nerve affection is well demonstrated in trigeminal neuralgia; where all the mucous surfaces which are supplied by this nerve, like those of the eye, nose, mouth, and tongue, assume the catarrhal condition, and there are cases on record in which the neuralgia was of sufficient intensity to produce inflammation and ulceration of the cornea—a condition similar to that which has been produced by Magendie in the rabbit by dividing the fifth nerve near the Gasserian ganglion. Now, here is one point to which I desire to draw special attention in this paper, and that is that we do not give sufficient consideration to perverted pneumogastric action as a factor in the production of pulmonary disease. We implicitly accept the teaching that no organ can preserve its integrity if its supplying nerve is diseased, but when we come to apply this principle of reasoning to the lungs in a state of phthisical degeneration, our intellect becomes dazzled by the bacillus theory and falls a prey to the strangest fancies and inconsistencies. This is astonishing, indeed, when it has been proven by a large number of experiments that by dividing the vagi, pneumonia of the catarrhal type, even to the extent of caseation, can be produced in animals, and that phthisis is continuously produced, and we have reason to believe, on a large scale, in the human being through the same channel. In a paper which I contributed to the *Medical News* for May 25, 1889, I supply reference to eighty-four cases (the clinical histories of which are in my possession) where vagus degeneration, brought about by the pressure of tumors, aneurism, by neuritis, etc., had caused various forms of pulmonary disease, such as œdema, bronchitis, pneumonia, and phthisis, thirty-seven of which belonged to the last classification; and it has been shown, too, by Dr. A. Lewin (*Beiträge zur Pathologie der N. Vagus*, Dissertation, St. Petersburg, 1888) that in the *post-mortem* investigation of twenty cases of phthisis he found the vagus diseased in every instance. We have, therefore, a definite record of fifty-seven cases of pulmonary phthisis dependent on vagus disease, besides that of many other forms of lung disease due to the same origin. Moreover, the vagus is not the only nerve which is involved in phthisis, for Dr. Jappa (*Zur Frage über die Verande rungen der peripherischen Nerven bei Sclewindsucht. Neurologisches Clbt.* Bd. 7, 1888, p. 425) found the peripheral nerves degenerated in the bodies of fifteen persons who died of pulmonary tuberculosis, and the same condition existed in quite a number of my own collection of cases, and this too in spite of the absence of any other symptoms than those which are commonly found in this disease during life. From these facts we learn, then, that not only the pneumogastric nerves, but the whole peripheral nervous system, as well, are seriously involved in the process which is known by the name of pulmonary consumption; and it remains now to show some of the causes which we know are actively engaged in destroying the integrity of these nerves and, therefore, in producing this disease. First among these causes I would place alcohol, not, perhaps, because it is more potent than many other causes, but because its action in this particular has been more thoroughly investigated. It goes without saying that the existence of an intimate relation between alcoholism and phthisis has long been suspected by those who are most familiar with these diseases. Let those who have any doubts on this point cast a retrospect over the family histories of the cases of consumption within their knowledge, and ascertain how often alcoholism prevailed either in the immediate or remote ancestry of their patients. I am convinced that this condition obtains quite largely among those who frequent our hospitals and dispensaries, and an abundant experience teaches me, too, that the evil is not confined to this class alone. In some of the districts of Paris, Dr. Alison[1] found that about one-third of those who suffered from consumption were also inebriates. It is not my purpose to weary you with reciting the records of such cases in order to illustrate this associ-

[1] "Archives Generales de Médecine."

ation, but a few typical ones[1] will, I think, suffice.

J. B., aged forty-two, began the excessive use of spirits after the death of his wife. He was a merchant, temperate, prosperous, and a man of character, but became a steady drinker, and was practically intoxicated all the time. His mother and two sisters died of consumption. His father died from injury, but his grandfather was asthmatic, and used spirits to excess for years. One uncle on his father's side died from excessive drink, and another one died of consumption. One uncle died from phthisis after many years of alcoholic abuse. His grandfather on his mother's side drank more or less all his life, and died from some rheumatic trouble.

C. H., aged forty-eight, an army officer, began to drink during the late war. His mother died of consumption two months after his birth, and his two sisters died of the same disease. His father's family is temperate, but several members have died of consumption. His grandfather on his mother's side was a sailor, and drank to excess at times.

George Ulmer came from England, in 1798, and settled at New Haven, Conn. He was a harnessmaker, a beer-drinker, and after middle life drank rum to excess, until death at sixty-one years of age. His wife was a healthy woman, and lived to eighty years of age. Eight sons grew to manhood and married. Six of them died of consumption under forty-five years of age. One was killed by an accident, and one died from the excessive use of spirits. Two daughters grew up and married; one died of consumption, the other in child-birth. They left four children; two were inebriates, and the others were eccentric and died of consumption. Of the children of the eight sons only ten grew up to manhood. Four of these drank to excess and died. Three of the six remaining died of consumption, and two others were nervous invalids, until death in middle life. The last one, a physician of eminence, has become an inebriate and is under care at present. He is the only surviving member of all this family. The male members of this family were farmers, tradesmen, and men of more than average vigor in appearance. They married women (so far as can be ascertained) without any special hereditary history of consumption or inebriety. (Dr. Crothers, *Journal of Inebriety*, October, 1888, p. 390.)

Now, it has been well established that alcohol has the power of causing a general peripheral neuritis in those who are addicted to its abuse, and it is in virtue of this power to disintegrate the pneumogastric nerves and the respiratory centers that it produces pulmonary consumption. The truth of this proposition I shall endeavor to show from the post-mortem records of the following abstracts of cases:

(Prof. Schultze, *Virchow's Archiv*, Bd. 108, Heft. 2; *Neurologisches Clbt.*, Bd. 6, 1886, S. 271.) Male, thirty-nine years old, developed diabetes insipidus in 1882, and was addicted to alcoholic excesses. Some time after 1882, he began to suffer from nystagmus, trembling in the arms, perversion of sensation (paræsthesia) in the legs, and from thoracic constriction. In 1886 violent attacks of dyspnœa developed, and death occurred in consequence of paralysis of respiration. Section: Degeneration of medulla oblongata and spinal cord, as well as that of the root of the vagus and hypoglossus. No account of the lung condition is given, but it is evident that these organs were deeply implicated since death occurred through pulmonary paresis.

(Prof. Strümpell, *Arch. f. Psych. u. Nervenk.*, Bd. 14, S. 339.) Male, forty-seven years old, a potator, was admitted November 25, 1881. Large and powerful frame, but both of his arms hang helplessly by his side; hands œdematous, skin and tendon reflexes wanting; legs weak and powerless; after a while œdema of lower extremities, cough, diarrhœa, dyspnœa; bronchial râles, paralysis of diaphragm and death, February 13, 1882. Section: Marked tubercular phthisis of both lungs. The radial, median, crural, and sciatic nerves were degenerated very decidedly, and Dr. Strümpell believes that the vagi and phrenics were also involved, although he failed to examine them very closely.

(Drs. Oppenheim and Siemerling, *Ibid.*, Bd. 18, S. 114.) Male, twenty-six years old, a potator, was admitted into Charité Hospital, January 17, 1881, on account of delirium tremens. He complained of headache, giddiness, and formication. On July 28, 1883, he suffered from complete impotence, lancinating pains, and rectal tenesmus. In August, he became subject to polydipsia and polyuria; on December 12, there was dulness in left supra-clavicular fossa, and infiltration of both apices, and tubercle bacilli were found in the sputum. He died the following August. Microscopic examination showed degeneration of the medulla oblongata, and of all the peripheral nerves that came under observation.

(Dr. Oswald Vierordt, *Neurologisches Clbt* Bd. 5, S. 421, 1886.) Male, aged thirty, much addicted to alcohol, and without a syphilitic history, suffered since March, 1884, with piercing, lightning pains in the lower extremities, as well as with weakness, unsteadiness, and formication in the same. He also developed phthisis and died the following March. Section: Pulmonary phthisis, and degeneration of the medulla oblongata, and the cervical and dorsal portions of the spinal cord.

(Prof. Thomsen, *Arch. f. Psych. u. Nervenk.*, Bd. 19, S. 191.) Male, aged forty-seven, a chronic alcoholic, was received, October 13, 1886, with delirium tremens. He was dizzy, unsteady in gait, but had no paralysis. Since the previous August he suffered from dyspnœa, distress in chest and in throat. Death occurred October 29. Section: Catarrhal phthisis. Cranial nerves somewhat grey. The nucleus of hypoglossus degenerated. The condition of the vagus root could not be definitely ascertained.

(Mr. Sharkey, "Trans. Lond. Path. Soc.," 1888, p. 27.) A female, addicted to the excessive use of alcohol, suffered from weakness, numbness, and cramps in the lower extremities, as well as from incoherence of speech. Respiratory sounds were harsh, and a few days after admission she had a rigor which

[1] These cases are abstracted from a paper on Alcoholism and Pulmonary Consumption which I contributed to the *Journal of Inebriety*, April, 1889.

was followed by a temperature of 102.8°, after which severe attacks of dyspnœa, paralysis of the diaphragm, and difficulty in swallowing occur. Respiration 40 per minute, and pulse-rate 140. Spitting of blood supervened, the lung apices began to break down, and she died after having been under observation nearly one month. Section: Tuberculosis of both apices and inflammatory changes in the phrenic, pneumogastric, and popliteal nerves.

So far it has been shown, then, that alcohol is not only a fruitful source of consumption, but that it brings about this disease by impairing the vitality of the respiratory nerves. In the next place, I shall make an effort to prove that syphilis, by vitiating the same structure—viz., the pneumogastric nerve and the medulla, is probably not less potent a cause in this respect than alcohol, as is shown by the histories of the following cases:

(Prof. Naunyn, *Archiv f. Klin. Med.*, Bd. 34, S. 433.) Female, nineteen years old, was admitted January 15, 1882, on account of syphilitic infection, when she stated that she had always been well until the previous May. Some time after admission she became subject to violent cough, dyspnœa, debility, night-sweats, weakness in the lower extremities, and marked shakiness while walking. Some fever, no œdema, and sensibility unimpaired; and at this time a physical examination revealed phthisical changes in both lungs. Death, July 18, 1882. Section: Phthisical degeneration in both lungs. The medulla oblongata and the cervical and dorsal portions of the spinal cord were diseased.

(Dr. Buss, *Arch. f. Klin. Med.*, Bd. 41, S. 241; *Clbt. f. d. Med. Wis.*, 1888, S. 195.) Female, aged twenty-nine, syphilitic, hemiplegic, suffered from disorder of speech, hearing, tasting, and seeing; also had dysphagia, and marked ataxia; and death followed seven years later from pulmonary phthisis. Section: Degeneration of lungs as well as of the medulla oblongata.

(Dr. Eisenlohr, *Clbt. f. Nonheilk.*, Bd. 10, S. 12.) Male, thirty years old, syphilitic, first complained of pain in both legs. Half a year later there was complete paralysis in the lower extremities, as well as lameness in the upper. Gradually his legs became subject to spastic contractions, tremor, etc., and he finally succumbed to acute phthisis. Section: Phthisical lungs, and degeneration of the whole spinal cord from the medulla to the sacral region.

(Prof. O. Kahler, *Prager Zeitschrift für Heilkunde*, Bd. 8, S. 1.) Male, twenty-nine years old, came under observation May 26, 1885. Two days previously he was suddenly attacked, while sleeping, with a peculiar sensation in the right side of his body, with disturbance of speech, and complete paralysis of left arm. On inquiry, it was found that three months before he had acquired a syphilitic sore. Examination showed that at this time the thoracic organs were in a normal condition. He was placed under energetic antisyphilitic treatment. During the last of August he began to complain of pain in the neck, spine, and thorax, diarrhœa and anorexia set in, and the patient died on the following November 10. Section: Small cavities in both apices, and degeneration of the medulla oblongata and cranial nerves.

(Dr. Berger, *Deutsch. Arch. f. Klin. Med.*, Bd. 23, 1879.) Male, aged thirty-five, admitted November 7, 1878, acquired syphilis four years before. He had a long and thin neck, and the cervical glands were indolent and swollen. Death, November 12. Section: Infiltration and caseation of both lungs. Left vagus diseased and imbedded in the enlarged glands of the neck.

(Dr. O. Vierordt, *Arch. f. Psych. u. Nervenk.*, Bd. 14, Heft. 3.) Female, aged twenty-three, contracted syphilis in 1880, and on October 3, 1882, she began to complain of weakness and of impaired sensibility in lower extremities. She developed all the symptoms of multiple neuritis, and at the end of November paralysis of the diaphragm set in, and death occurred the following December 19. Section: Pulmonary phthisis. Spinal cord normal. The peripheral nerves had undergone intense degeneration, especially the phrenic and right sciatic. The right vagus and left sciatic were atrophied.

These six cases of syphilitic phthisis show a great deal more than that which they indicate on the surface. None of them were investigated and recorded with any other object than that of ascertaining the influence of syphilis on the nervous system, and the lung complications were only noted incidentally. Therefore, when we reflect that this form of phthisis is comparatively common, especially among certain classes, it may be taken for granted that the production of phthisis by syphilis through the instrumentality of the vagi could be found more frequently than it is, if efforts were made to look for it.

It must not be thought, however, that alcohol and syphilis are the only agents which have the potency to bring about pulmonary consumption through the mediation of the nervous system. In my collection of cases, to which reference has already been made, there are records which show that lead, brass, diphtheria, scarlatina, measles, etc., are capable of acting in a similar manner. Indeed, the more thoroughly the pathology of phthisis is studied the more transparent becomes the supreme folly of ascribing it to a single cause, like the tubercle bacillus. From a correct interpretation of the testimony in this paper, it is obvious that a germ is not necessary to the evolution of this disease, and that anything which has the power of violating the integrity of the nervous system, and especially that of the vagi, must be regarded as a veritable cause of pulmonary comsumption.

Viewing the origin of consumption from such a standpoint, it is clear, in a measure, at least, why the savage is so much more liable to this disease in his first contact with civilization than he is in his native state. The whole question of civilization resolves itself essentially into one of adaptation. In the succession of geological ages only those species of animals survive who have the power of adjusting themselves to the changed relations. The same holds true of man in a social state. When the powerful vices of the white man's civilization are suddenly thrust upon the Indian, his moral and

physical nature sustains a terrible blow; and if, in spite of his sufferings, he did not have the splendid capacity of adapting himself to his new environment, which he is known to possess, he would certainly go down in the contest. It is universally admitted that rum and syphilis—the Indian's worst enemies—are two of the greatest curses which have ever been transmitted from a higher to a lower civilization. It seems a travesty on Supreme justice, but it really appears to be the outcome of a general law. Our own Indian is no better off in this respect than is the Indian of Alaska, Australia, and New Zealand, or, I fear, than is the African in this country, or in his native land during his first intercourse with the white race. Now, statistics amply confirm the opinion that while he is in this transition stage, the consumption death-rate of the Indian, as well as that of the African, is much greater than that of the white man, or than it is after they both become acclimated to their new condition. That alcohol and syphilis are wholly responsible for this result I do not for a moment believe, but that they are to blame for a large proportion of it I think is evident from what has been said on the subject.

Such is the disease. What is the remedy? The inductions of this paper teach that in order to prevent pulmonary consumption it is not only necessary to prohibit all alcoholic and venereal abuses, or to proscribe all injurious occupations like those which pertain to lead, brass, etc., but it is absolutely essential to look beneath the surface of things and endeavor to ascertain any latent tendency which may have been originally induced by these causes. I do not know how far-reaching the inherited influences of lead poisoning may go in this respect, but the examples which have been cited in the foregoing pages lead us to believe that those of alcohol extend at least to the second generation. And so far as syphilis is concerned, it may be stated that some of the most eminent authorities in medicine—among whom was the late Prof. S. D. Gross—entertained the view that scrofula and consumption were only a refined and modified form of syphilis. This may be an extravagant assumption, but it nevertheless serves to show the suspicion that syphilis is in some way closely related to the propagation of pulmonary consumption, and in estimating the probabilities of this disease in any individual case this element must not be left out of consideration. In consonance with this line of action we must not lose sight of the fact that diphtheria, scarlatina, measles, etc., also occasionally act as exciting causes of consumption, and that we must, therefore, carefully watch the convalescence of those suffering from these diseases. So, too, we must teach our people to protect themselves against "colds" and malaria; nor must we forget to treat the nervous, and especially that form of nervous disease known as hysteria, for the histories of Prof. Grasset's forty cases[1] of hysteria show that this disease is very intimately associated with pulmonary consumption.

[1] "Brain," Vol. VI, p. 433, and Vol. VII, pp. 13 and 161. A number of these cases are quoted in my two lectures on Pulmonary Consumption as a Neurosis.—*Therapeutic Gazette*, November and December, 1888.

Reasoning, therefore, from the manner in which these powerful causes induce consumption, it is quite clear that the way to prevent this disease consists in maintaining a good tone of the whole nervous system, and of the pneumogastric nerves in particular, and the most successful way in which this can be accomplished is by keeping the bodily functions normally and actively employed; for we know that exercise lends strength, while a lack of it entails weakness and disease. This is not such an easy matter as it appears, for the lungs, as we have already seen, afford more respiratory surface than is necessary to carry on the function of respiration; hence, in the great majority of individuals, especially in those who follow sedentary occupations, it is absolutely necessary to constantly employ some artificial measures whereby this innate tendency towards pulmonary idleness may be overcome. This is such an important matter that all such persons ought to place themselves under the guidance of a teacher in gymnastics who appreciates the proper relation between the lungs and the rest of the body. If under such a course of training there is produced a good expansion of the apices I am quite free to say that the liability towards pulmonary consumption is reduced to a minimum. It may happen, but I never saw good apical expansion and chronic infiltration coexist in the same lung. On the other hand, when such training cannot be procured, I would recommend voluntary forced breathing in connection with well-regulated movements of the arms. The person is to stand erect, and the arms being used as levers, are swung backwards as far as possible on a level with the shoulders during each inspiration, and brought together in front on the same level during each expiration. Or the hands are brought together above the head while inspiring, and gradually brought down alongside the body while expiring. When a deep breath is taken in accordance with either plan, and held until the arms are gradually moved forwards or downwards, or even much longer, the process of chest expansion is materially enhanced.

Another very effective chest exercise is to take a deep inspiration, and during expiration only, the individual will, in a loud voice, count as long as he possibly can. A male person with a good chest capacity can count up to sixty or seventy, while in a female with good lungs even this power is somewhat reduced. Practice of this sort will gradually develop the lungs, and the increased ability to count longer is a measure of the improvement going on within the chest. All of these movements may have their effects greatly enhanced by the use of dumbbells, chest-weights, etc., which are made especially for the purpose.

Bodily exercise has an important bearing on this question. The power of walking is common to most people, and its influence on the lungs, as we have seen, is very marked. Running, dancing, skipping rope (especially when the rope is swung backwards), bowling, etc., are all to be highly recommended. Whatever the mode of exercise may be it must be performed under as little compulsion as possible. One reason why the above-named exercises are so

conducive to health consists in the fact that the excitement which they produce is so attractive that the consciousness of muscular effort is lost.

In this connection I desire it to be clearly understood that I only think of advising such treatment for those who are comparatively well, and not for those who are suffering from the disease under consideration. I confess that my opinion on this point has undergone a radical change during the last few years—a change which has forced itself upon me by the logic of circumstances. I believe that many consumptives are irretrievably injured by the mistaken notion that they must have plenty of exercise. This brings me into a field, however, which I have no right or desire to invade at present, and I must desist; although the temptation to pursue it is greatly fascinating.

The breathing of compressed and rarefied air is also attracting wide attention as a means of improving the capacity of the chest. This method has already achieved marked success in Germany, where it was first introduced, and there can be no doubt that it will meet with equal favor among the profession in this country so soon as its merits are more generally understood.

Now, what of the corset and of abdominal constriction? Are these practices so injurious to health as they are reported to be from certain quarters? The answer to this question depends upon the essential question as to how shall the female support her clothing? Practically, so far as I am able to see, there are only two ways in which she can do this—one to support her clothing from the waist and the other from the shoulders. There can be no doubt that both are injurious, in a measure at least—the former by constricting and compressing the abdominal organs, and the latter by interfering with the free movements of the upper part of the chest; but it is a question of a greater or lesser evil. If a lack of apex expansion is such a strong predisposing element in the causation of consumption, as we have been led to believe, and if, on the contrary, a fully developed apex motion practically excludes this disease, then anything that she may do to counteract such development will directly increase her liability in this direction. If the male by supporting his clothing from the shoulders interferes with the free and full expansion of his lung apices, then this interference is greatly aggravated in the case of the female, because the clothing which she has to carry is generally two and three times heavier than that of the male. That the female loses her costal type of breathing by refusing to wear a corset, and by suspending her clothing from the shoulders for a protracted period I have repeatedly demonstrated with the pneumograph, but whether she becomes more liable to consumption than her corset-wearing sister, and which, from *à priori* grounds, we have reason for believing, we do not have the necessary statistics to decide. Although in countries like Prussia and Switzerland, where statistics of the comparative liability of the two sexes to pulmonary consumption, both in country and in city life, exist, it is demonstrated that the consumption death-rate of the female is higher in the country than in the city. Whether this has any connection with corset wearing and abdominal constriction I do not know, but experience teaches me that corset wearing is less customary in the country than it is in the city, and it is also true that, as a rule, the costal type of respiration is more pronounced in the city than it is in the country females.

Now, while not desiring to encourage tight lacing, I believe that on the whole, at least so far as pulmonary disease is concerned, the female is better off if she wears her clothing from the waist instead of supporting it from the shoulders. I believe, too, that the male would be vastly benefited were he to support his clothing in the same way. No teacher of gymnastics would tolerate anything like suspenders to support the clothing of those under his training, and if he gets his best results in bodily development in this way I think his methods will bear imitation.

SPLENIC FEVER.

By B. F. LAMB, A.M., M.D.,
PHILADELPHIA, PA.

SPLENIC fever is a disease of malarial origin, having its center of irritation in the spleen, and maintaining the same relation to this organ that remittent fever holds towards the liver. It may be classed as a continued fever, and distinct from splenitis in being a non-inflammatory disease, and, consequently void of the symptoms of either local or general inflammation.

In point of history and distribution, splenic fever, being a malarial disease, may be said to have existed synchronously with malarial poison, and to be found in localities infested with miasmata throughout the globe, but more especially in warmer latitudes. It is also most frequently encountered in damp and ill-drained situations, or such as are prolific of typhoid fever, malarial meningitis and hemorrhagic fever. In this country it is especially frequent in the marshy sections of the Atlantic and Gulf coasts, where malarial diseases are found in great variety of complication and with frightful virulence and fatality.

The symptoms of splenic fever in many respects resemble those of typhoid, and have been frequently mistaken for those of the latter disease, while some have regarded it as a hybrid of typhoid and remittent, and have styled it "typho-malarial." The first appearance of the disease is a feeling of malaise and muscular debility, which are followed within a few days by the active symptoms of chill and fever, as in ordinary remittent, with which it is often complicated.

The chill, usually occurring in the morning, is light, unattended by rigor, and often scarcely perceptible, save by the sudden rise of fever, which ascends to a temperature of 104° F. in the evening, but gradually declines to 100° F. or less at the expiration of twenty-four hours. The fever is then without remission, succeeded by another paroxysm. The pulse-rate varies from 100 to 120 per minute, with reduced arterial tension. There is thirst, anorexia, moderate nausea, constant headache with some vertigo. There is no pain or soreness in the thoracic

nor abdominal viscera, excepting the spleen, nor is there any apparent disturbance of the functions of the liver, kidneys, nor of digestion. The tongue is coated, but moist and otherwise normal in appearance. The urinary secretion is healthy, excepting an acid chemical reaction and moderate diminution in quantity. The biliary secretion remains undisturbed, as indicated by complexion and condition of the secretions, while the area of dulness is unchanged, nor is there increased sensibility of the liver. The functions of the heart and lungs are normal, as shown by both objective and subjective symptoms.

The spleen, on the contrary, manifests morbific disturbance to a greater or less extent. There is soreness with supersentiveness upon palpation, with or without enlargement. There is, however, no evidence of an inflammatory process, nor of the development of abscess, or other product of inflammation, as swelling and induration; but merely symptoms of irritability, which continue for an indefinite period and disappear with the subsidence of the fever. The patient prefers the dorsal or left lateral decubitus, never the right, which increases his sense of discomfort but produces no pain. The disease is attended by a general feeling of debility followed by rapid emaciation much resembling typhoid fever in general aspects. There is no stupor, tympanites, nor iliac tenderness, but, on the contrary, a continued wakefulness, with short and unrefreshing sleep, and a consequent condition of nervousness and mental apprehension not attributable to any special morbific irritation of the brain or nerve centers. There is also supersensitiveness to atmospheric influences, from which cause a chill may be induced at any moment.

The duration of the disease is from three to six weeks, though it may be prolonged to three months. It is peculiarly prone to recurrence or to relapse, and though not necessarily a fatal disease, the frequent relapse or annual appearance of the attacks may lead to a fatal issue, through physical exhaustion, rather than organic paresis.

Excepting the great debility experienced, the patient is not conscious of any special suffering, and will attempt to arise from his pillow only to return after a brief interval; he will also wonderingly interrogate as to the cause of the continued debility and the probable limit of the same; or feeling confident of ultimate recovery may discharge his physician, who is sure to be recalled to find the patient unimproved.

The treatment of splenic fever is based upon that of the malarial diseases generally. While sulphate of quinine reduces the temperature, yet it fails to control the exacerbations of fever, and a persistence in its use induces gastric irritation. Alkalinity of the blood and secretions is accomplished by the administration of potassium bicarbonate, while a quiet sedation will be secured by the exhibition of opiates. Potassic and other bromides are not tolerated in quantities sufficient to accomplish the latter result. Antipyrin and antifebrin possess little advantage over quinine in splenic fever, being also open to the objection of increasing gastric irritation. Locally, the unguent hyd. rub., alternating with strong counter-irritation proves beneficial. The use of mineral acids is pernicious, as they prove a direct irritant to the spleen, increasing its volume and tenderness and intensifying the fever. The internal use of the mercurials is useless. While stimulating and nutritious foods are highly essential, the confinement of the patient to a warm and dry atmosphere, with other appropriate hygienic surroundings, is indispensable to a sure and steady convalescence.

In conclusion, it may be added that while this disease has been often mistaken for other and kindred ailments under the guise of malarial modification, it is nevertheless incumbent upon the practitioner thoroughly to analyze the symptoms from a multitude of complications, not only in order to insure his own efficiency and success, but also in order to discharge his sacred duty in maintaining in the light of exact science the standard of the noblest of professions.

MALARIAL PNEUMONIA.

By J. P. FRANCEZ, M.D.,
CARENCRO, LA.

MALARIAL pneumonia has been very rife during this present spring, 1889. The severe type manifests itself, first, by several paroxysms of intermittent or remittent malarial fever. Pneumonia will then set in with slight rigors, followed by headache, flushed face, soreness in the chest, aching in the limbs and back, with tight, dry painful cough. Fever averages about 103½–104° F. Examination of the chest reveals an alteration in the affected side; a bruit rougher than on the opposite side. A whole lobe is usually involved, beginning indifferently and in about equal proportion, either at the base or the apex.

Frequently the crepitant râle is not dry at the end of the act of inspiration, and is often substituted by bronchitic respiration. There is bronchophony—"le souffle dans l'oreille or voilé" of Laënnec.

Percussion gives negative results or a light alteration. Sputa vary from frothy mucus to the pathognomonic ones of classical pneumonia.

The paroxysm generally continues for thirty six or more hours; the fever then abates or intermits and with it the chest troubles. Should the case be intermittent a few scattered râles will be found by auscultation; in the remittent type, the bronchitic respiration is ameliorated, and we have the redux râle.

Resonance is either normal or almost so during the apyrexia, in the paludal form. A general perspiration ends the fever.

After a couple of hours of respite the paroxysm sets in anew, with chest symptoms, much more severe, and remits once or twice again, after thirty some hours each, making the case last from the onset to the end of the attack, five or six days.

When the case ends by death, the fever and chest troubles go on increasing after the breaking of the second paroxysm; remission, if there is any, is light. The respiration is much embarrassed, hurried, and laborious; the pulse is thready, 120 and more; temperature soon reaches 105°, and the patient dies bathed in a cold, clammy sweat. Or, when both lungs have

been affected, one after the other, at the subsidence of the troubles, when hopes of recovery have been expressed, another chill comes on, and without further warning the physician discovers a double pneumonia, which rapidly ends in death. I have seen a lady, multipara, with a double malarial cataleptic pneumonia. The chest and nervous symptoms increased and decreased with the febrile movement; she died on the seventh day. This case was of the remittent type; temperature 100°–105⅕ F. Chances in double pneumonia are half and half; and with children about three to one.

The treatment must be directed to the cause. Quinine is the specific and should be pushed to full physiological action, and the sooner the better. The noble brute, malarial bacillus, will be flushed from its lair to jump into the next lung; continue your chase with your quinine pounder and eight times out of ten you will have the advantage of your microscopic man-killer. There are certain subjects whose skin is very sensitive to quinine; to these give the ext. cinchona, from five to fifteen grains every third hour in whiskey.

Cough syrups or mixtures, turpentine stupes, hot fomentations and dry cups may be of service. Nauseants, antimonials, depressant means should be discouraged. Blisters seem to ignite the fever without influencing the pulmonary trouble. Calomel, with or without opium in combination, has also fallen into disuse, probably not without reason. Experience has gradually demonstrated the minor degree of power which it was at one time supposed to possess in aiding the absorption of exudations, and no valid proof has been afforded that the duration of pneumonia has been shortened by its use. By most of its advocates it was only held to be efficacious after the previous employment of venesection and the administration of tartar emetic, and a remedy requiring such antecedents is one that may with advantage be abandoned. Keep the bowels open by mild laxatives.

It seems to me that when I combined the sulphite of sodium and quinine the disease was stopped sooner, but my experience is too limited to guarantee it as a therapeutic means. I combined the two drugs on account of measles prevailing throughout the country.

This is a résumé of fourteen years' practice.

JEFFERSON COLLEGE.

HEMORRHOIDS.

TREATING hemorrhoids by ligation is, I think, not to be commended. The method, in the first place, is slow and painful, and again it is by no means devoid of danger; thrombosis may occur from a little embolus formed at the point of operation, or septicæmia may result, either of these complications being sufficiently dangerous, and both having occurred often enough to inspire caution.

Generally speaking, clamping the hemorrhoid and applying the actual cautery is the best method. The danger of hemorrhage is thus avoided, for the eschar does not fall off till there has been an effectual occlusion of the severed vessels; and as to antisepsis, what better antiseptics are there than the heating followed by the charcoal?

If after any operation on the rectum there should result such hemorrhage that it cannot be controlled by the ordinary means, I have found this a good way: Tie a stout cord to a cup-shaped sponge and pass the sponge up the rectum with the convexity above, now pack the rectum well with some material, draw on the string till firm compression is made, and this can be made continuous by fastening the cord to a stick or other object placed across the buttocks.—*Nancrede.*

HARE-LIP.

This patient is a young woman of some eighteen years, and is unfortunate enough to be afflicted with hare-lip. This deformity is exceptionally calamitous in one of her sex, for they have no means of concealing it.

She has already had an operation performed, but it was a miserable failure, and that fact makes a second operation more difficult and its success more uncertain. I shall make a lozenge-shaped incision, thus:  with the upper legs of the lozenge the longer. By bringing together the freshened edges, a slight pouting is produced below, just what we wish.

I am proceeding with great deliberation as you see, and this is the main reason that hare-lip operations of the present day are more successful than they formerly were, that more time is taken.

If there is a difference in level between the two sides of one-sixteenth of an inch, it can be noticed; and my experience has been that those who have tried to make a so-called "brilliant" operation of this —finished it with a few quick cuts and several hasty stitches—are more likely to make a brilliant failure. I am accustomed to take the pins out in from forty-eight to seventy-two hours, and if I think the parts still need support to give it by placing across the incision a little cotton and covering with collodion.

—*Nancrede.*

STATISTICAL.

9318 physicians look after the sick of Pennsylvania.
8248 are graduates.
932 have no diplomas.
230 have bogus diplomas.
316 are women.
2009 come from the Jefferson.
1945 " " " University.
470 " " " Hahnemann.
140 " " " Woman's College.
21 reside in Forrest County; or, 1 to 208 inhabitants.
9 live in Elk County; 1 to every 1422.
8 live in Potter; 1 to 1724.
Philadelphia has 2099; 1 to 405.
Average for State, 1 to 459.

RECITATIONS *VS.* LECTURES.

TWO different movements with regard to the education of the medical student are undergoing discussion at the same time, which are directly opposed one to the other.

In England some circles are advocating the further imposition of the study of phonography on the already overloaded student of medicine, whilst the New York *Medical Record* has an editorial rather discountenancing the lecture system with its attendant consequences, and suggesting an adoption in medical schools, in part at least, of the method of recitations customary in ordinary schooling.

To be able to write shorthand with any degree of fluency requires much time and laborious work, and even then only those who make a business of phonography can take down *verbatim* a lecturer's words. This, of course, is what is expected of the medical student, for if merely an abstract be wanted, that can easily be taken in long hand. In a movement of this kind it is proper to ask, *cui bono?*

We have noticed that the first-course student generally arms himself with note-books, some the size of a ledger, and writes most earnestly and persistently through all the long lectures, as if he were listening to the wisdom of Solomon—truths, which, if he did not at once indite, would be forever lost to him and to the world. By the second year he has discovered that much of the substance of these lectures is to be found elsewhere; and by the third year the truth dawns upon him that of what he hears but little is not already in his books, and he then contents himself with taking a small note when he thinks the teacher has made a point. A short pencil and a little blank book will usually suffice.

This is what he should have done in the first year, for the student who simply listens attentively to a lecture will remember more than if he tries both to listen and write.

The tendency of the more advanced schools in this country is to substitute lessons and recitations for lectures, at least during the first and second years; and we believe it is only a question of time when such a course will prevail through the whole medical curriculum. If common and high schools, academies and classical institutions, have found the system of teaching by recitation the best, there is no reason why it should not also be the best way in which to teach medicine. We fail to see anything in the study of medicine that requires a different treatment.

The didactic lecture must go. It is nothing but a relic of past years, when students had no books to refer to, and must needs get their information *per verbum oris*. With the advent of multitudes of works on every imaginable medical subject, such a reason no longer exists.

Didactic teaching would be an interesting and good method provided the lecturers were teachers, but they are not always. There is hardly a school in the land that numbers in its faculty more than three or four teachers; often not that. Some more or less eminent man is called to a professorship, he writes his notes, appears before the class to read them, and, *mirabile dictu!* he is called a teacher.

Teaching is an art and a difficult one. Few are born to it. The art is one usually to be gained only by special study and long practice, whereas most of the lecturers in medical schools never taught a day in their lives until they appeared before a class in the capacity of teacher.

Reading, too, is an art, fully as difficult as that of teaching. The majority fail here also; reading all the way from indifferently well to miserably bad.

The days of didactic medicine are coming to an end, and instead of talking about phonography, let lessons and recitations displace the system now in vogue; give the student, in methodical manner, his regular stint of work each day, and he will then be able to accomplish far more than under the present haphazard desultory plan, or rather lack of plan.

Annotations.

THE *Druggists' Circular* continues the attack upon us, which was opened by its manager at Newport. We desire to say at once that every statement and insinuation therein made concerning the TIMES AND REGISTER is utterly and unqualifiedly untrue. Neither manufacturers nor patent medicine houses own or control our company. It is not a trust and has no designs upon its contemporaries. The absorption policy suggested only exists in Lillard's imagination. This, and the impudent attempt to represent the TIMES AND REGISTER as favoring substitution, are simply intended to create a little prejudice against our enterprise in the minds of publishers and advertisers.

One thing is demonstrated by the publication in the *Circular*, and that is, that its manager's action is

adopted by the journal itself, and hence, that the latter's standing, professionally and morally, is to be gauged by that of Benjamin Lillard. To those who are familiar with this personage's career, no further reply to his insinuations is requisite; to others, we will say that the unblushing mendacity of the editorial in the *Circular* removes the matter into a region into which we are unable to follow. We can hold no controversy with a man who has no reputation to lose and whose statements are bounded only by the fertility of his imagination. We trust that our readers will relieve us henceforth from the obligation of denying any future charges from the same quarter.

NON BACILLAR PHTHISIS.

IT was with considerable surprise that we heard Dr. S. Solis-Cohen, in his remarks on Dr. Wilson's paper at Newport, quote approvingly Niemeyer's remark, that the greatest danger to a consumptive was that he might become tuberculous. The last time we heard Dr. S. speak upon the subject of phthisis, he was the exponent of those who forsook the paths of pathology and cast aside the results of thought and of experience to run after the *ignis fatuus* of the day. He was then vaunting the superiority of the germicidal therapy, giving iodoform by the mouth and pumping sulphuretted hydrogen into the rectum. We would much like to know the present views of those who were exploiting Bergeon's method two years ago. Do they ever use it now? Or has its utility vanished with its novelty? Does it still produce that remarkable amelioration in all the *symptoms* of this dread disease, at two dollars a puff?

We are glad to see evidences of the profession's returning to its senses. Our knowledge of pathology is certainly defective; yet we do possess enough to warrant us in judging new ideas and newly-discovered facts by the light of what has preceded them. To us, who have steadfastly adhered to Niemeyer's teachings concerning phthisis because they harmonized with clinical observations, the strongest proof of the causative influence of the tubercle bacillus lies in the fact that it harmonizes so well with his descriptions of true tubercular phthisis. Not one word of his classical description needs to be changed; but Koch's discoveries simply give an explanation of facts which no recent writer has described more accurately than Niemeyer had already done before Koch's time. The great clinician described a form of acute phthisis which is simply inflammatory and one which is tuberculous. The former explains the cures occasionally reported.[1] Of chronic consumptions he describes three: first, a chronic pneumonia, with hypertrophy of connective tissue, contraction, bronchiectasis, etc.; secondly, a true tubercular affection, which may occur primarily; or thirdly, as Dr. Cohen expressed it, appear as an epiphenomenon in the course of a pneumonic phthisis. We have learned to attribute this outbreak to an invasion of the pulmonary tract by the bacillus tuberculosis; but in no particular has the description of Niemeyer become obsolete. Nor have we made any material advance upon his methods of treatment, except in the way of prophylaxis. We have unquestionably multiplied the number of agencies which we may utilize in treatment, but we scarcely secure any better results. The prevention of the spread of disease, by segregating the patients, and by the disinfection of sputa and other discharges, constitute at the present day the sole practical results of the discovery of Koch's bacillus. In every phase of its application the germicidal treatment has proved a failure, whether used in the shape of direct applications to the tuberculous lungs, or by saturating the body with germicidal substances.

SUBSTITUTION—A CARD.

BY one of those mistakes which, we are assured, occasionally happen in even the best regulated families, an annotation slipped into one of our late issues which was worded in such a manner as to give rise to misapprehension. It scarcely seems necessary to say that neither the TIMES AND REGISTER, nor any member of its editorial staff, favors or desires in any manner to condone the wrong of substitution. Our record in that matter is certainly clear, and there is scarcely a medical journal in the country which has not quoted approvingly our editorial condemnation of this practice, and defence of the physician's right to prescribe whatever he considers best, and the pharmacist's duty to give exactly what is ordered, no matter what his individual opinion thereupon may happen to be. We have even gone to the trouble and expense of having special examinations made of the various pepsins and fluid extracts in the market, and demonstrated the necessity under which the prescriber rests of designating the manufacturer upon whose fluid extract he is basing his dosage; as, in the case of belladonna, we found a diversity ranging from .18 to .58 between the samples tested.

The writer of the annotation headed "A New View of Substitution," had no thought of defending the manufacturers of Febriline, whoever they may be (we do not know the parties, and have no advertising or other interest in them), in what was an undoubted wrong; the selling of one thing under the name of another. Even if commercial quinine does contain, as is claimed, a portion of quinidine, this is also a wrong, and does not constitute a valid reason for their action. The writer of the paragraph labored under the hallucination that his item was ironical, and that he was making a very passable poke at himself and his brother physicians when he suggested that they were themselves doing the very thing they so strongly objected to in the case of the druggists. Like Mark Twain's celebrated joke about the Indian statue, however, this one seems to have been so far fetched that nobody saw it; and our highly ethical friends of the *Druggists' Circular* grasped at once, and thankfully, the opportunity to place us in a false position. We have notified our brother to send diagrams with his jokes in the future; and in the meantime hasten to assure our readers that we haven't been seduced by the wily manufacturer to depart from our freely outspoken detestation of the roguery of substitution.

CIRCUMCISION ENFORCED BY LAW.

THIS is the title of an article in *Daniel's Texas Medical Journal*, by a colored physician, Dr. Vandavel. The writer accepting as true the statement that the Hebrews have particular immunity from disease, and that four out of every five males suffering from venereal taint have elongated prepuces, suggests the propriety of legislation having in view the abscission of this redundancy. There is also an æsthetic side to Dr. Vandavel, for he naïvely remarks, that the "elongated prepuce does not add anything to the looks of the organ."

For the double purpose, then, of avoiding in a measure venereal diseases, and of adapting the human body more accurately to the canons of high artistic taste, Dr. Vandavel holds that it should be cut off.

The editor of the Journal goes a step farther, or, if you please, not quite so far, in commending this as a measure to be applied exclusively to the colored race. This scheme might have been practicable "befoah the wah," but we seriously doubt whether the colored voters of the country would favor such legislation, even though it might have the effect of approximating them more nearly to the ideal physical man.

Letters to the Editor.

FEEDING OF INFANTS.

MEDICAL journals are intended to disseminate useful instructions to all classes of practitioners both young and old. I occasionally see an article written for the benefit of the profession which I feel like criticizing, not that I think I am better posted than the writer, but that the writer has not studied his particular case thoroughly. Friendly criticisms do no harm, and on the other hand sometimes are beneficial.

I have just finished reading a clinical lecture styled, Feeding of Children, and published in THE TIMES AND REGISTER, for June 29, 1889. While there are many good points made by the lecturer, there are some that will hardly stand the test of experience. He says "there is an old custom to nurse a child for eighteen months, but I do not adhere to it, as it ought to be nursed off and on for a year. When it is eight months old it should receive some artificial food."

After nearly forty years active practice and most of the time largely in childrens' diseases, it has not been my experience that a child needs or ought to have artificial food at eight months of age. A child requiring artificial food at this age, does so on account of the inability of the mother or nurse to furnish the needed supply, either in quantity or quality. If the mother is strong and able to stand the drain the child should *not at eight months receive artificial food.* He says, "it is much better for the mother, as the constant nursing is a drain on her, and you have no business to allow this." Why should this be so serious a matter with the mother? Let fashion, mode of eating, and the food eaten, answer. The discussion covers more ground than could be devoted to it in this paper.

He says, "I think cow's milk is as good as the milk of the ass or goat when properly prepared."

In this preparation, is where all the trouble lies. The food must contein all of the elements of the child's body, or some of the tissues will be found wanting. These are all found in healthy mothers' milk, and if possible the mother should nurse her child until the appearance of the double teeth; or until the child is eighteen or twenty months old. He says "the milk of the cow is heavier and denser than the mother's and must be diluted by a *certain* amount of water; and this is the first step in its preparation. Take good healthy cow's milk and dilute with three parts of water and you have the right proportion." It is conceded by most writers that cow's milk contains three times as much cheese, less than twice as much butter, less sugar and less water than mother's. Our artificial foods will take the place of human milk just in proportion as they agree with or imitate its character. In human milk the proportion of caseine to the butter is as 100 to 170; in cow's milk it is as 100 to 105. The reason of this is plain; cow's milk is made for the young ruminant, who is not only expected, but is able to follow its mother; and in order to do this must have food rich in nitrogenous material to develop its muscular system; and it will run and play when it is two days old. With the human infant it is far different. It cannot follow its mother; but the mother goes to the baby when it requires food, and it has but little or no use for muscular development the first year of its life; but it requires food rich in heat and nerve building material, with the proportion of 170 to 100 of nitrogenous. With this in proportion of 105 to 100 as in cow's milk, can you expect to succeed? Again, can you by any process of dilution with water arrive at the same constituents as mother's milk? It is plain that by no process of dilution with water can this be accomplished and made a substitute for human milk. There will be in every case an excess of caseine or a diminution of butter and the effort will fail. The proportions of the constituents of the cow's milk must be changed to correspond to that of human milk, before it can by any means become suitable food for babies. Again it is a fact that food has to answer two distinct purposes, the one to furnish material for growth of the body, the other to furnish material for the maintenance of its temperature. Food that is not thus supplied will not support the system in a proper manner any length of time. Again, he says, "When the child is seven or eight months old it is time to give it something else than ordinary milk; then comes in the various preparations of infant foods. It is not my purpose to advertise or use any one particular food, but when used you can incorporate it into milk and begin with ʒj–ʒvj of prepared food according to the age and strength of the child."

He does not tell us which kind of food to select. Some of them no doubt are better than others. Dr. A. thinks he will try Ridge's food, with its 70 per cent. of starch. This food is prepared from wheat and, as I have before stated, must accomplish two things, the growth of the body and the maintenance of a

proper temperature. These are contained in human milk in the proportions of one to two, while in wheat they are as one to seven, and in the majority of Dr. A.'s cases he is doomed to disappointment. Dr. B. selects Carnrick's food. He adds starch to his cow's milk to bring up the carbonaceous principle until it is as 170 to 100, as in mothers' milk. How about this material for growth? Supposing the child able to digest it, here it is as one to twenty-six. You have not the right proportion and Dr. B. has trouble. The facts are, your artificial food must contain not only the materials, but they must be in proper proportions, the same or nearly so as contained in human milk, or it is evident that your efforts will in all probability fail.

He says, "one of the best substitutes for cow's milk is condensed milk." What is condensed milk? It is cow's milk with the water evaporated and an excess of cane sugar added to it, and when you replace the water you have the same milk that was used in the beginning, containing all of the impurities, tyrotoxicon, etc., etc., which it at first contained. Again he advises lime water in babies' food. Any alkaline carbonate taken with the food will, to the extent of its power, neutralize the natural acidity of the gastric juice and impede digestion; then why tell the young man to use it in his baby food? If your patient's stomach is sour, lime water between meals, to neutralize this acidity, would no doubt do good, but with food never.

Feed your babies as near as possible, according to the following: Place the cow's milk, of which you intend to feed the child (using night's for the day, and morning's milk for the night), in as many perfectly clean dishes as you expect to feed the child, times out of that milk; never go to the same dish the second time. Let the cream rise, and for a baby at birth take nothing but the cream, and to this add, according to the richness of the cream, from twenty to thirty parts of water that has been boiled, or enough to make it look bluish. As the baby grows older take a little milk with the cream and less water.

A child at three months of age can take with the cream, the upper one-eighth of the milk, and the older the child gets the more milk and less water, until at about ten months the child can take clear cow's milk.

Watch the discharges from the baby's bowels, and if they contain curds, take less milk, more cream and water.

At ten months the child may be fed beef, scraped fine, slightly cooked and salted or seasoned. This, with the milk of the cow, with a small allowance of sound, well ripened fruit, should constitute its sole diet until the coming of the double teeth. Then, and not till then, is the child capable of digesting starchy food. Milk prepared in this way contains all of the constituents of human milk; and if care be used it will contain the same equivalents. We change the proportions of carbonaceous to the nitrogenous, so that it is the same as in human milk, using the cream to do it with and not resorting to starch or any hydrocarbons, thereby retaining or maintaining the material for heat and the material for growth as per nature's formula. This is very simple. By taking the upper part of the milk we get the butter, which the baby requires, leaving the cheese in the pan. Sugar of milk should be used instead of cane sugar, for two reasons; first you are imitating nature, second it requires no chemical change in its equivalents and will not ferment as readily as cane sugar. For thirty years, both in clinics and in hospital as well as in private practice, I have been governed by the above rules and I am thoroughly convinced they are correct.

DR. D. M. COOL.
Late of South Side Dispensary, Children's Department, Chicago, Ill.
FARIBAULT, MD.

MONTGOMERY WHITE SULPHUR SPRINGS.

I WRITE you a few lines in regard to this region, but little known to Eastern people, and yet worthy of a visit, and close study. It is primitive in its arrangements of the cabins, or wooden cottages; which are situated around the pavilion of the Springs at short distances from the dining and ball rooms with the offices near. The rooms of these cottages are whitewashed, have comfortable beds, dressing tables, washstands, and a few chairs. The shades are not on rollers but nailed up, and the windows of the cottage we occupied had to be fixed by the carpenter before they would shut or open, and when open had to be propped up with a piece of lath.

When we arrived from Roanoke, which is a pleasant place to break the journey from Philadelphia or New York, being some twenty-eight miles distance, and the train of the Norfolk and Western Railroad starting, at 10 A.M., we found the ball rooms filled with pretty girls and many handsome men, dancing the German, a very fair string band with cornet, etc., making good dancing music. This was kept up until dinner hour, at half-past one. The dinner was fair, not extra good.

The Allegheny Spring is celebrated for its antidyspeptic waters, which are bottled and sent all over the country. There are about two hundred and fifty persons at the Montgomery Springs, principally from the extreme South, there being but one Northern family, registered from Philadelphia.

This place is one of great natural beauty, situated in a lonely valley, surrounded by mountains and yet on an elevation of two thousand feet and almost always having a delightful dry breeze passing through this valley even after the long spell of rainy weather.

The waters consist of three sulphur springs, one chalybeate, and a freestone spring for washing and bathing, clear, pure, and free from impurities. Suitable arrangements are made for cold, warm and sulphur baths. The components of the waters are chiefly sulphates of soda, lime and magnesia, with a large amount of sulphuretted hydrogen, the water clear, bright and sparkling, of an agreeable taste and quite cold. It is a valuable diuretic and diaphoretic, diminishing abdominal plethora and congestion of the liver, kidney, and portal circulation, useful in incipient tuberculosis and chronic rheumatism, also in skin affections and constipation.

There are numerous springs in this vicinity, one of

which we have already referred to, and still another very little known in the East, namely the "Virginia Thermal," arsenic bromine and lithia, which contains, according to the analyses of Henry Froehling, .06974 of lithium carbonate, .00571 sodium iodide, and .01557 sodium arseniate, with numerous other valuable ingredients. The temperature of the water of the springs is 69° F. This spring is located in Montgomery County about seven miles from the Norfolk and Western Railroad, at Shawsville. Looking at the analyses it will be found by comparison to be 109 per cent. stronger in arseniate of soda than the Thompson Springs, and 0.57 stronger than the Ashley Springs of North Carolina. In addition to a very good proportion of lithia, which makes it useful in a large number of kidney and other affections, it also contains the sulphates of magnesia and soda, rendering it mildly laxative and valuable in the treatment of indigestion and irritable stomach. Its alterative nature renders it of the utmost value in what is understood as the strumous diathesis, more commonly known as scrofula. In conjunction with these waters the change in diet, air and exercise, conduce much to the cure of such chronic cases.

CINCINNATI LETTER.

TUBERCULOSIS in sleeping cars was the subject discussed by Dr. J. T. Whittaker, of Cincinnati, on invitation of the Surgeons of the New York, Pennsylvania and Ohio Railroad, at their recent meeting at Lakewood, N. Y. The doctor, who is Professor of Medicine in the Ohio Medical College, brought out many new, original and practical thoughts. As it had been shown that dysentery killed more men in war than the enemy's guns, so he thought it would be shown that disease is more frequently contracted in railway cars than do accidents happen. The last few years have given the startling revelation that the disease, if it cannot be absolutely cured, can be absolutely prevented. The doctor did not believe in the theory of heredity, and proceeded to demolish this idea. To the lungs we must look for the primary affection in the vast majority of cases, and if to the lungs to the air which enters them. The closer the room, or the more crowded the apartment, the greater the danger of infection. Hence the frequency of the disease in factories, convents and prisons. The mortality in prisons in the last years of a long confinement amounts to 90 per cent. Ziemssen says, indeed, that imprisonment for ten or fifteen years is condemnation to death from tuberculosis.

It would be difficult to conceive, says the author, a conjunction of circumstances more favorable to the dissemination of this disease than is offered in the palace car. It is always badly ventilated, the vestibule car especially is close and hot, sixteen to thirty persons being crowded into a space which might make a small hall but never a bed-room for a pair of human beings. Somebody is always hurt by a draught and windows are kept closed, to prevent free ventilation as well as the ejection of sputa, which is mostly deposited on the floors. Cuspidors never contain water, and the temperature is raised to a degree which is sufficient to rapidly disseminate infectious matter. When the shades of evening appear the bedding is opened out and diffuses through the apartment a disagreeable odor. The bacillus is treated to the luxury of clean sheets and pillow cases, but the blankets, mattresses, carpets, and worst of all, the curtains, remain the same till worn out. Consider that every car curtain is, or has been, occupied by a consumptive patient, if only en route for a change of climate; and if tuberculous matter become deposited on the curtains, bedding, etc., what becomes of it, if it be not dried and disseminated through the car, or gradually incorporated into the lungs of the tired traveller? The danger in some respects is far greater in ships' cabins, but then you have the escape to the upper deck, while in some express trains we do not even get out into the fresh air for our meals or other necessaries of life. The ship passenger may mount to the deck, the prisoner is allowed a part of each day to walk in the free air, but the passenger on an express train is, for all the world, in the condition of dogs inclosed in boxes made to breath atomized tuberculous matter, until even dogs, naturally immune, become infected with the disease.

Now for the remedy. The plush, velvet and silk hangings must go. Seats must be covered with smooth leather that can be washed off. Carpets substituted with rugs to be shaken at the end of each trip, or better still dispensed with altogether in favor of hard wood floors. In place of curtains, screens of wood or leather; the blankets of invalids' beds to be subjected to steam at a high temperature, mattresses covered with oiled silk or rubber cloth that may be washed off, and, above all things, invalids provided with separate apartments, shut off from the rest of the car, with the same care taken to exclude the far less offensive and dangerous smoke of tobacco. Cuspidors half filled with water, and consumptives provided with sputum cups which can be emptied from the car. The sole and only danger lies in the sputum and its destruction abolishes the disease. The patient protects himself from auto-infection in the sound parts of his lungs. Is it not wise to look to the construction and management of sleeping cars, and may they not be death-traps in more ways than one?

PARALDEHYDE IN ASTHMA.

PARALDEHYDE in half-drachm doses has proved a most valuable remedy in my hands in cutting short the paroxysms of asthma. I have tried it repeatedly with the happiest results. But a combination of remedies often acts nicer, and the following combination has never failed to give immediate relief to that troublesome affection:

℞.—Tinct. ipecac. comp. . . . . gtt. xvj.
Sp. ammon. aromat. . . . . ℥j.
Paraldehyde . . . . . ℥ij.
Sodii nitrit. . . . . gr. v.
Aquæ menth. pip. . . . . q. s. ℥j.—M.

Sig.—Teaspoonful in sweetened water every half hour till relief is obtained.

R. T. SCOTT, M.D.

WAVERLY, MO.

IDIOSYNCRASY FOR IPECAC.

A RATHER singular instance of idiosyncrasy for ipecacuanha happened the other day in a patient, a woman of some thirty-two years. For indigestion, with eructations of gas and bitter taste in mouth, I gave her this mixture:

℞.—Sodii carbonatis . . . . . gr. xlv.
Vini ipecacuanhæ . . . . . ♏xlv.
Ext. rhei fluidi . . . . . f℥iss.
Aquæ menth. pip. . . . . ad ℥iij.—M.
Sig.—Teaspoonful in hot water before meals.

In this preparation there was slightly less than two drops of the wine of ipecacuanha, yet she complained that shortly after taking each dose she felt her face flush, her head become hot and dizzy, and she grew so sick that she was forced to lie down for some time. The last dose she took before coming back had the further effect of partially blinding her, or rather of making her hypermetropic; for in order to thread a needle, for instance, she had to hold it about two feet from her eyes.

I have recently heard of another case in which a mixture of otherwise innocent drugs, containing in each dose two and one-half minims of syrup of ipecacuanha, produced violent nausea, vertigo and vomiting, and marked injection of the conjunctivæ with bile.

ERNEST SANGREE, M.D.

Book Reviews.

THE URINE, THE COMMON POISONS, AND THE MILK. By J. W. HOLLAND, M.D., Professor of Medical Chemistry and Toxicology, Jefferson Medical College, Philadelphia. Third edition, revised and enlarged. Philadelphia: P. Blakiston, Son & Co., 1889.

In the preface the author says that his little volume is intended as a syllabus for the laboratory, and with that end in view the book is in a convenient shape for slipping in the student's pocket. Blank leaves are left for calculations and memoranda.

The arrangement of the matter is good, and the printing neat and legible.

A SURGICAL HANDBOOK FOR THE USE OF PRACTITIONERS AND STUDENTS. By FRANCIS M. CAIRD, M.B., F.R.C.S. and CHARLES W. CATHCART, M.B., F.R.C.S., Assistant Surgeons, Royal Infirmary, Edin. Pp. 262. Price, $2.50 Philadelphia: P. Blakiston, Son & Co., 1889.

This is a compact, small volume with a flexible back, and capable of being carried conveniently in the pocket. The book is written principally for those who are engaged in active surgical work. It is well arranged, with good headlines and full index, so that any desired subject can be referred to in a moment.

A large number of illustrations of various surgical apparatus and procedures, most of them especially made for it, adorn the volume.

Massage receives a chapter, and there is also one on the Surgical Applications of Electricity.

The general subject of orthopædics is well treated and illustrated.

A chapter is devoted to the examination of the urine, and an appendix containing a variety of valuable instructions completes the book.

THE POPULAR SCIENCE MONTHLY FOR AUGUST, 1889. New York: D. Appleton & Co.

The August number of *The Popular Science Monthly* opens with an article on The Spirit of Manual Training, by Prof. C. H. Henderson, who says that if the manual training school escapes being dominated by mere shop-skill as well as by mere book-learning, it will furnish the best all-around education yet devised. There is another paper in this issue on Agnosticism and Christianity, by Prof. Huxley, in which he reviews the chief points of his controversy with Dr. Wace, and sharply criticizes some of Cardinal Newman's writings. Life in the Solomon Islands is described by Mr. C. M. Woodford, with a number of pictures. As the natives of this group are head-hunters, life with them seems to have some uncertainties. A similar article is Savage Life in South America," by Captain John Page. A. G. Warner, Ph.D., discusses Scientific Charity, and maintaisn that scientific methods applied to charitable work will merely guide our sympathies and not thwart them. The Influence of Race in History is pointed out by M. Gustave Le Bon, who shows that it explains why one conquest led to a brilliant civilization and why another brought in an era of disorder. Mr. W. H. Larrabee describes The Stone Age in Heathen Sweden, with illustrations of many implements and structures of stone. Samuel Sheldon, Ph.D., contributes a paper on Electrical Waves, describing recent experiments which indicate that electricity is conveyed in waves like light. Felix L. Oswald, M.D., has a suggestive article on The Wastes of Modern Civilization, in which he points out that the resources of the modern world are being used up with little regard for their replenishment, or in making useless and even harmful products. In The Defensive Armor of Plants, M. Henry de Varigny describes the various means plants have for protecting themselves against their enemies. Prof. John F. Woodhull has a good word for Home-made Apparatus, which he says is more generally available and more effective than complex and expensive contrivances. The customs of Blood-vengeance and Pardon in Albania are described by Herr J. Okiê. Under the title Mr. Mallock on Optimism, Mr. W. D. Le Sueur criticizes the recently expressed opinion of that writer that no hopeful outlook for the race is furnished by science. A sketch and a portrait are given of Lavoisier, who is remarkable both for his important work in chemistry and the tragic ending of his career. The scientific lessons of The Johnstown Disaster are pointed out in an editorial, and the other departments are marked by their usual variety.

SECONDARY MIXED INFECTION IN SOME OF THE ACUTE INFECTIOUS DISEASES OF CHILDREN. A Thesis read before the Chicago Gynæcological Society, January 25, 1889. By BAYARD HOLMES, M.D., Attending Surgeon, Cook County Hospital, etc., etc. Reprint from the *North American Practitioner* of February, March, and June, 1889.

Dr. Holmes, in this masterly thesis, reviews the infectious diseases of childhood, with especial reference to the active part taken by the microörganisms, as demonstrated by recent bacteriological research. His study embraces all of the graver sequelæ of measles, scarlet fever, and mumps.

The Medical Digest.

INCONTINENCE OF URINE IN CHILDREN (Descroizilles).—

Sulphate of strychnine . . . . . 0 gr. 05
Syrup . . . . . 96 gr.
Water . . . . . 4 gr.—M.

To be given in tablespoon doses: one to twenty a day.

Strychnine . . . . . 0 gr. 05
Conserve of red roses . . . . . 2 gr.

Divide into 20 pills. Take one to four a day.

Ergot of rye . . . . . 2 gr.

Divide into 10 parts: one to three a day.

Ergotine . . . . . 2 gr.
Powdered licorice,
Syrup, āā q. s.

Divide into 20 pills: two to five a day.

Bark and leaves of rhus aromaticus toxicodendron . . . . . 200 gr.
Alcohol, at 800 . . . . . 800 gr.

Prepare by displacement. A tincture will be obtained of which the dose will be from ten to sixty drops a day.

—*La Bulletin Médicale.*

RECTIFIED ESSENCE OF TURPENTINE IN CROUP.—Dr. Lewentaner, of Constantinople, reports four cases of idiopathic croup when the symptoms were so severe as to afford but little hope for recovery. As in each case tracheotomy was refused he determined to follow the treatment of Dr. Demolow, and administered the rectified essence of turpentine in tablespoonful doses. The symptoms promptly ameliorated and recovery followed in each instance. He also makes use of the following spray:

Essence of rectified turpentine,
Tinct. of eucalyptus . . . . . āā 4.0
Phenic acid 300.0
Alcohol 300.0
Distilled water 1000.0

To be used in atomizer night, and day.

—*Bulletin Géneral de Thérapeutique.*

FATTY DEGENERATION OF THE HEART (Kisch).—

℞.—Powdered rhubarb root,
Extract of aloes . . . . . āā 2 grammes.
Extract of jalap,
Extract of trefoil, q. s.

Make 30 pills: one to be taken at night.

If anæmia coexist the following pills are useful:

℞.—Sulphate of iron (very pure) . . . 3 gram.
Aqueous extract of aloes . . . . . 2 gram.
Extract of trefoil, q. s.

Make 30 pills. Take one pill night and morniug.

In addition, a diet calculated to excite urinary secretion should be ordered.

If indications of a sluggish circulation should be present, digitalis is indicated in combination with a purgative.

℞.—Powder of rhubarb root,
Aqueous extract of aloes,
Powdered digitalis . . . . . āā 2 gram.
Ext. of trefoil, q. s.

Make 30 pills: one every three hours. At the same time, and in order to increase the cardiac energy, wine or spirits should be administered; but cutaneous injections of ether may also be employed.

—*Revue de Thérapeutique.*

INJECTION FOR UTERINE CANCER (Cheron).—

Tincture of iodine . . . . . ½ drachm.
Salicylate of soda . . . . . 2½ drachms.
Tar water . . . . . ½ pint.

Dissolve: three to six spoonfuls in a pint of warm water.

—*La Gazette Médicale de Montréal.*

POWDER STAINS ON THE SKIN.—The bluish-black spots produced by gun-powder may be removed by painting with the following solution:

Biniodide of ammonium,
Distilled water, equal parts.

Then with dilute hydrochloric acid to reach the tissues more deeply affected.

—*Revue de Thérapeutique.*

LACTOSE, A NEW DIURETIC IN DISEASES OF THE HEART.

BY PROF. GERMAIN SÉE.
Translated by ALBERT E. ROUSSEL, M.D.

The most infallible of diuretics is milk; this quality as well as that of being a complete aliment, causes it to assume a very important role in the therapeutics of diseases of the stomach and in diseases of the heart.

In diseases of the stomach it is especially suitable when we have present an excess of hydrochloric acid, as it fails utterly in the contrary class of cases.

A large number of physicians, as Chrétien, Serres, Pécholier, have confirmed its importance in dropsies of renal as well as of cardiac origin.

Milk in the dose of from three to four pints a day does in effect render the greatest services in dropsies due to disease of the heart, especially when the patients have a normal stomach or one containing an excess of hydrochloric acid.

It constitutes in effect a complete food; unhappily it does not contain fat, casein and sugar in proper proportions.

Two and a half pints of milk will suffice to give one hundred grammes of necessary fat, three pints would be necessary for one hundred and twenty grammes of the albuminoid substance, and at least five pints for the two hundred and fifty grammes of the hydrocarbons. During the period of rest three pints of milk contain sufficient of the albuminoids, but will not suffice for a healthy man who works.

Milk is easily digested. Unfortunately this digestion will not take place in patients suffering from heart disease, in which cases it is probable that the normal lactic ferment of the stomach is absent or diminished.

Milk diet produces an evident diuresis and a glycosuria.

This diuretic function is due to the lactose, a discovery made by M. G. Sée in experimenting with the different constituents of milk. Sugar of milk exists in all milks; it crystallizes easily and is soluble in six parts of cold water and two and a half parts of hot water. It is formed in the organism at the expense of the albuminoid substances, and when the dose absorbed is not too large it loses its individuality by oxidization.

Lactose is the most principal and the most reliable of the diuretics actually known. In addition if two pints of milk are given we obtain all the advantages

of diuresis without any of its inconveniences; that is to say that there does not follow, as with milk, a diabetic poluria.

From the dose of one hundred grammes diluted in two pints of water and with complete suppression of all other liquids, milk, broth, wine, mineral waters, etc., there is obtained a considerable increase of urine in all sick persons, in all heart cases irrespective of the nature of the lesion; degenerations, alterations of the aortic valves, etc. This action is less noticeable in arterial sclerosis.

Twenty-five patients, seriously sick, were observed with care, and there was obtained in the twenty-four or forty-eight hours after the beginning of the treatment a veritable urinary flux of 2500 grammes at the least, but amounting generally to 3200 or 3500 grammes; in two cases especially M. Sée obtained 4000 and 4500 during two and four days respectively. As soon as the treatment was suspended the urine returned to its original quantity.

At the end of his communication M. G. Sée formulated the following conclusions:

Lactose constitutes the most powerful diuretic and at the same time the most inoffensive. It is this and this alone which imparts to milk its diuretic property. The other constituents of milk, especially the water and the salts, have no manifest action on the urine, the chloride of sodium does not add to the polyuria due to the sugar of milk, and the salts of potash are but a secondary cause.

Milk in the quantity of two pints does, it is true, produce diuresis, but at the dose of four pints, of which each contains fifty grammes of lactose, it causes at the same time a very evident glycosuria, a passing diabetes. At the same time there is produced a considerable excretion of urea indicating a destruction of the albuminoids. Sugar of milk permits us to avoid all these inconveniences and dangers; one hundred grammes of lactose in solution will produce an enormous diuresis which we could not be certain of obtaining with four or five pints of milk. In the milk the action of the lactose is hindered by the casein and the fat.

The increase of urine resulting from the use of one hundred grammes of lactose exceeds that produced by all other medicaments; it rapidly reaches two and a half pints of urine and increases nearly constantly to three pints and a half, and even four and a half on the third day. After this time it remains stationary or decreases by two and a half pints during several days. During this time the dropsy disappears almost to a certainty, the blood becomes freed from the hydrocarbons, and it is due to this cause that the diuresis is not as intense as at the commencement. We can state that lactose acts in a sure manner in dropsies of cardiac origin, but in those due to a renal trouble the action is more doubtful or even *nil*. In affections of the heart it fails only in those where the kidney has become involved and when the albumen amounts to 0 gr. 60 to 0 gr. 90 per pint. As long as the quantity of albumen is a minimum the result is favorable, which leads us to suppose that in these cases there is a simple venous stasis. We can measure by the lactose diuresis the degree of alteration in the kidney.

The diuretic action may be interrupted by causes other than renal. We have present at times a diarrhœa which naturally diminishes the diuresis. In other cases the patients had for a greater or lesser period of time profuse sweats or accidental transpiration which lessen the polyuria, but it soon reappears.

This medicament, as a rule, is perfectly well supported. It should be prescribed during eight or ten days and interrupted for several days, after which it should be repeated. If exceptionally, it should not be well taken, we may add brandy or mint water. We should diminish or suppress all other liquids.

Lactose presents an immense advantage, it permits the patient to take all kinds of aliments, it permits the doctor to prescribe flesh diet, or nutrition in a different way and often indispensable to sustain the failing forces of the patient.

Now, that these facts are acquired, it is necessary to explain the mode of action of this new diuretic, which we may call physiological. We know that the diuretics act often by means of the high blood pressure; here the pulse and pressure remains normal. The alkaline salts are considered as producing their diuresis by their osmotic power. Now, after adding two grammes of potash to the tisane lactosique, there is nothing more than from the lactose alone. We must admit an elective and selective action on the secreting elements of the kidney; it is a physiological renal diuretic.

If we compare it with other diuretics we find the following: Those which augment the pressure, digitaline, convallamarine, strophanthus, and others yet to be determined, act much more fully, less surely, less efficaciously on the dropsies than does lactose. Bucquoy with his traditional loyalty and true scientific spirit recognized the superiority of lactose as compared with strophanthus, the medicament of his adoption.

A second group of diuretics, was the only one well established until now, which includes the renal diuretics, properly called, at the head of which is placed caffein. They form part of a chemical series which commences with xanthine and finishes with caffein. We already know these things:

1. That caffein and theobromine are nephritic diuretics like lactose.

2. That both act indepenently of the vascular pressure.

3. That they have no true action on the heart as has recently been pretended, and in this also they resemble lactose. But caffein produces nervous and cerebral trouble of which lactose has never been guilty.

We have, therefore, in lactose the diuretic of heart affections in the asystolic period, the true curative means for dropsies of cardiac origin, even those which have resisted other agents. During the asystolic period there is another accident more serious, dyspnœa, but against this lactose is powerless, and, therefore, its action should be seconded by iodide of potassium. This medicament, which I discovered ten years ago, aud which has been stolen from me since with much enthusiasm and perseverance, by changing, under pretext of its toxic effects, the name of potassium into sodium, constitutes by it iodine and potassium the true medicament for the heart and for

the circulation. It only lacks a diuretic power. Combine the iodide and the lactose and you fulfil all indications.

Incontinence of Urine. Cure by a New Operation.

In 1883, a girl, aged fourteen years, was admitted to the Rudolfinerhaus suffering from congenital and continuous dribbling of urine. According to her mother's statement, an unsuccessful attempt at an operation had been made when one year old. Upon examining the genital parts, a normal introitus vaginæ was found, containing an annular hymen. The meatus urinarius was in the normal position, but very wide, forming a fissure, which became gradually more and more shallow, as it extended all the way to the anterior commissure of the labia, between the widely separated halves of the clitoris. The urethra, scarcely 1 cm. in length, easily admitted the little finger. Of a former operation there was no trace.

This, then, clearly was a case of epispadias, in which the sphincter vesicæ failed to form a complete circle, or had not been developed at all. In the hope of restoring the continuity of the sphincter and thereby its function, I removed a narrow strip of mucous membrane from the anterior or upper wall of the urethra, extending from the meatus to the bladder, and also freshened up the cleft, splitting the clitoris, and united the edges of the wound thus made with fifteen interrupted silk sutures, four of which were inside the urethra.

The wound healed by primary union, and during the first three days the patient's condition was improved, being better able to retain the urine while in the recumbent position. But after four days the old condition had returned, the improvement having been due simply to the swelling of the mucous membrane, temporarily reducing the lumen of the urethra.

The operation devised by my colleague, Dr. Pawlik (*Wien. Med. Wochenschrift*, 1883) was now done, and at my request, by Dr. Pawlik himself, requiring three sittings. Fourteen days after the last sittings the patient could retain the urine for two consecutive hours, but only in the recumbent posture, whereupon she was discharged.

But in October of the last year the patient, now nineteen years old, and fully grown, returned and applied for readmission, not being satisfied with the result of the former operation; she was able while sitting to hold her water for over an hour, but suffered from constant dribbling while standing or going, and sometimes even while in the lying position.

A new operative plan now became necessary. The sphincter, evidently present only in a rudimentary way, could not be relied on after the failure of the first operation; and the operation of Rutenberg, complete closure of the urethra, with the formation of an abdomino-vesical fistula, could be thought of only as a last resort. I conceived the idea to turn the urethra upon its lineal axis, feeling sure that a urethra thus twisted would be furnished with a reliable *elastic* closure, and that the difficulty of adjusting the firmness of this elastic closure to the strength of the detrusor urinæ could be overcome only by experiment upon the patient herself.

The first operation was done October 3, 1888. A circular incision was first made around the orificium exterum urethræ. Proceeding from this cut, the urethræ was separated from the circumjacent tissue, but in such a manner as to leave attached thereto a layer of tissue of considerable thickness, in order not to interfere too much with its nutrition. In this way the urethra was dissected out, until up under the pubic arch, when at last I had before me a tube attached to the neck of the bladder about 2 cm. in length. Before beginning the operation a thread was tied in the edge of the meatus in order to mark the position. The urethra thus separated was now twisted around its long axis, in the direction of the hands of a clock, so that its external orifice was turned to the extent of 180°, and fixed in this position by proper suturing, after I had convinced myself that there was no considerable resistance to the passing of an elastic catheter. On the seventh day the sutures were removed, the urethra found fastened in its new position, and continence secured to the extent of 80 ccm.

During the following days the continence was improved to the extent, that while lying or sitting, the urine could be retained for several hours and to the amount of ¼ liter, but while standing up the dribbling continued as before, thus proving that the elastic resistance of the urethra attained by the operation was still insufficient. Therefore, October 26, three weeks after the first operation, the procedure was repeated, the urethra dissected out to the length of 1 cm. turned 90° further, in the same direction as before and fixed in that position by means of sutures.

Thereupon followed retention of urine for two days, but after this the voluntary voiding of urine became possible. While lying or sitting the urine could be retained to the amount of about 200 ccm; but while walking about for only ten minutes the closure became relaxed, and the result was still far from satisfactory. On November 27, one month after the second, the third operation was undertaken. As before, the urethra, with abundant surrounding tissue, was separated to the length of nearly 2 cm, turned around its long axis in the same direction, and this time 180° further than the second time, and fixed in this position with seven silk sutures, after being convinced that a quite thin elastic catheter could be passed through, meeting with but slight resistance. It will thus be seen that the three operations involved a turning of the urethra to the extent of one and one quarter of a circle, equal to 450°.

After this last operation followed retention of urine lasting for three days. After November 30 the catheter was no longer necessary. On the eighth day the sutures were removed and primary healing had occurred. The urine could be retained for three hours while lying or sitting, and only five minutes while going about, when intense pressure and desire to urinate occurred, *but no more dribbling*. On December 19, three weeks after the last operation, the patient was discharged. The retaining capacity of the bladder at this time was 500 gr. In two to four hours occurred irresistible pres-

sure and desire to micturate, which, assisted by considerable bearing down effort, required from five to ten minutes time to accomplish.

About the last of April, 1889, the patient was last heard from, when she reported that she could retain the urine five hours, that the act of urination required four minutes time, and that the quantity voided was about one-half liter.

—Dr. *R. Gersuny*, Wiener Centrblt. für Chirurgie, No. 25. June 22, 1889.

Paul Bourget believes that pepsin is not so frequently the cause of indigestion as is commonly assumed to be the case; but that on the other hand, there is often a deficiency of hydrochloric acid. He formulates the following conclusions:—

1. Pepsin is very often quite useless in the treatment of gastric affections.

2. The practitioner will do well to pay more attention to the presence of hydrochloric acid. He should ascertain whether it is found in excess, or whether it is abnormally diminished; also whether its secretion is retarded. This knowledge will then furnish valuable indications for treatment.

3. Pyrosis is caused by the formation of lactic acid, and not the routine employment of alkalies.

4. Alkalies should never be administered except at a period when stomachial digestion is already finished.

Extirpation of the Pancreas and Diabetes.—M. Minkowski has just completed a series of experiments consisting in the complete extirpation of the pancreas in the dog, the rabbit and the pigeon.

The result obtained was a production of a diabetes mellitus. This diabetes which exhibits itself in from ten to twelve hours after the operation, presents in the dog all the symptoms found in the human being; it continues without interruption until death, and, notwithstanding a superabundant alimentation, a progressive emaciation and lack of nutrition is observed.

The authors affirm that the solar plexus as well as the adjoining parts were left absolutely intact, so that the diabetes must be exclusively attributed to the removal of the pancreas.—*La Tribune Médicale.*

Belgium and her Insane Institutions.—Clark Bell, Esq., *Medico-Legal Journal*, contributes an interesting article on this subject.

It seems that the proportion of insane to the rest of the population is about the same in Belgium as in this country, though they are not confined in asylums, as is well known, but are taken charge of by different families. This method has been productive of excellent results.

In the district of Gheel there are some 1800 insane patients, living one, two, or three in a family, and in eleven years there have been but one case of crime by the insane, only three or four illegitimate births, and only one of these ascribable to a lunatic.

The author admits that there is ordinarily a great difference in temperament between the Belgian and the American, the latter being more unsatisfied, irritable and nervous, yet he thinks that before building more of our costly asylums we should do well to consider the feasibility of introducing this system into the United States. Dr. Blumer, for instance, superintendent of the Utica Insane Asylum, says that about 70 per cent. of his patients could with safety be placed with farmers and others on the Belgian plan.

Contraction After Burns.—J. H. Webb contributes to the *Australian Medical Journal* an article worthy of attention. He claims that in burns of superficial but rather extensive character, and located at points of flexure, radical measures are to be advocated. These lesions are very slow in healing, running away up into the months; and even after the healing process is completed, what is the result? A right angled knee- or elbow-joint or firmly flexed fingers. The parts may be kept straight for months by the use of splints, but as soon as these are removed the inevitable contraction begins, and an unsightly embarrassing deformity occurs.

He cites several cases in point: A match set fire to a man's trousers, and the skin covering the popliteal space, that of the lower fourth of the thigh and of half the calf of the leg was charred, so that it sloughed away. After lying in bed some nine months with his leg in splints the man was discharged, his leg being straight.

He shortly reappeared among the out patients with this member at a right angle. He was again admitted, tenotomy practised, the patient finally leaving the hospital worse than before. Long before, he had lost his first good position as foreman in an oil warehouse, and now, on account of this troublesome and unwieldy right-angled leg he could find no employment except that of time-keeper in an establishment at a mere pittance. To complete his history of woe, a boy one day ran against the leg that stuck out from the artificial one and the man sustained an extra capsular fracture of the thigh. Result—three more months in a hospital. His affairs now became involved, he lost his house, and is now a "hopeless, helpless, poverty stricken cripple."

Several similar cases are related by the author, who closes by asking whether immediate amputation would not be far preferable, and whether in view of the ultimate and common results of large superficial burns, surgeons are not generally too much inclined to conservatism for the real good of the patient.

Surgical Notes.—The Brooklyn Throat Hospital, a new institution incorporated a few months ago, was formally opened Wednesday, June 19. There were a great many prominent physicians present. After thoroughly inspecting the hospital, which is located on the corner of Bedford Avenue and Fifth Streets, the guests adjourned to Hotel Bosworth, where dinner was served, followed by speeches.

Medical News and Miscellany.

EDISON says that an alternating current of 1000 volts is certain death.

NEURALGIA of the supra-orbital nerve is often caused by eating ice-cream too fast.

DYSENTERY prevails epidemically at Carthage, Ill., and at Hamilton, Canton, and Kohoka, Mo.

DR. GEORGE F. SHRADY, editor of William Wood & Co.'s *Medical Record*, has a cottage at Pine Ridge in the Catskill Mountains.

DR. F. W. MCRAE assumes the management of the *Atlanta Medical and Surgical Journal;* one of the best journals in the South.

WHILE gathering a small crop of hay on his farm, near Newport, Del., Dr. Alexander Irons, a retired practitioner, died of sunstroke.

RUSSIA has fixed doctors' charges. Physicians making $450 per year will get 45 cents per visit; others 25 cents. In country towns 10 cents is the usual charge.

DR. EDMUND S. T. ARNOLD, of New York, has a cottage at Newport, but it is understood that he has been obliged to close it this summer on account of the illness of his daughter.

A NEW hospital is to be placed in the Annexed District, New York, north of One Hundred and Seventy-fifth Street, near Third Avenue. The ambulance corps will respond to all calls north of the Harlem.

DR. EDWARD FRANKEL, of New York, after a service of fifteen years as visiting surgeon to Charity Hospital, has been appointed consulting surgeon to that institution by the Commissioners of Charities and Corrections.

THE *Doctor*, New York City, devoted to the physician in his relations to the community, and to physical development, dietetics and hygiene, price $1.00 per year; with the TIMES AND REGISTER, and DIETETIC GAZETTE, $3.00.

THE medicinal treatment for gout, now almost universally recommended for whoever has it, has been enjoined upon the Queen by her physician, Sir William Jenner. She must give up champagne and claret, and drink whiskey and Apollinaris.—*Times.*

ONE of the most charming of the ladies' magazines is "*The Home-Maker*," edited by Marian Harland. In the August number the editor contributes "A Word to Wives," and a very sensible word it is; like all Marian Harland's words. "Pet Lore for Pet-Lovers," by Walter Satterlee, will be appreciated by many who love the so-called inferior animals.

All the articles are much shorter than magazine articles usually are, and let us say that it is a very difficult matter to fill a journal with short articles, as acceptably as those before us. The magazine is published monthly by the Home-Maker Co., at 19 West Twenty-second St., N. Y., at $2 per annum.

WORD comes from Norwich, Conn., that Dr. M. H. Mason, one of the oldest and most popular physicians in that place, will sell the old homestead, Riverside, which has been in his family for many years. The climate of Norwich is unfavorable to the doctor's son, so another place of residence is to be chosen.

THE Philadelphia Board of Health has taken steps to correct the system of death registration, by which the wards in which hospitals are located are credited with the deaths that occur in the hospitals. A regulation was adopted directing that death certificates from hospitals shall give the residence of the deceased.

THE drop-a-penny-in-the-slot water coolers found here and there throughout the city will hardly become popular, at least with the intelligent; for no one who knows a tithe of the danger in drinking from a public cup, will put his lips to one without a careful washing of it. But as for these cups, scarcely enough water comes from the cooler to fill the vessel, not to speak of rinsing it.

A MOTHERS' AID SOCIETY has been formed in Philadelphia for visiting sick poor children and getting them out to the Park. The following young ladies are members: Miss Belle MacKenzie, of South Thirty-sixth Street; Miss Kate Birmingham, of Haverford Road; Miss Ellen Martyr, of North Fortieth Street, and Miss Bessie King, of North Thirty-ninth Street.

THE death of Dr. J. Lewis Smith, Jr., of New York, on Monday, July 8, of heart failure, cut short a promising career. His father is clinical professor of diseases of children at the Bellevue Hospital Medical College, where the younger man received his diploma in 1884. At the time of his death Dr. Smith held a position in the New York Infant Asylum and also gave his services in the out-of-door department of Bellevue Hospital.

DR. CORNELIUS J. DUMOND, of New York, who was sued not long ago by Gerritt Smith, on the ground that the doctor had treated him unskilfully, has secured a victory. At a trial before a justice and a jury, a verdict for $1000 damages was given the plaintiff, but the judgment has just been reversed by the General Term of the Supreme Court. The judges declared that there was not the least evidence of unskilful treatment, and a new trial was ordered.

TYPHOID IN KENSINGTON.—Cesspools that have not been cleaned within the memory of the oldest inhabitant, sewers that empty their decomposing and noxious materials into the Delaware at the water's edge and a water supply pumped from the same river within two hundred yards of the mouth of one of the largest and foulest of these sewers, form a combination of causes that would account for epidemics enough to depopulate the district. No intelligent person can read Dr. Randle's report without arriving at the conclusion that the typhoid, like the poor, will be always with the people of Kensington while present conditions exist.—*Times.*

The leading question with trained nurses just now is, whether their employers are justified in requiring them to take their meals with the servants. There is but one answer to this question: "Certainly not!"

Dr. James P. Boyd, of Akron, Ohio, has been recreating at "The Prospect," Asbury Park. Mrs. C. A. Child, the proprietress of this hotel is a well-known New Yorker, and her house is one of the best in Asbury Park. It is situated on Wesley Lake. The guests are entitled to free boats, and are supplied with water from a fine artesian well.

The statements of William Walter, an attendant at the Blockley Hospital, concerning the manner in which post-mortem examinations are held in that institution cannot but harrow the feelings of persons whose unfortunate friends have died in the hospital, and whose bodies have passed under the surgeon's knife. "After a 'post' I generally collect all the the parts that belong to the bodies," Walter said. "When I come to the last one, if there is anything left over I put it in there. Sometimes there are three 'posts' at one time, and I find it difficult to keep track of the organs, but I put them back as near as possible.—*Record.*

Dr. Laurence Johnson, of New York, is making an ocean voyage this month, returning immediately by the steamer on which he sails from this port. It was expected that the ceremony of laying the corner-stone of the new building of the New York Academy of Medicine would take place on July 17, and Dr. Johnson was to deliver the address, but masons and contractors decreed otherwise, and the date was changed to the 23d inst., so that, unfortunately, Dr. Johnson will not be present.

It is doubtful when the new building of the New York Academy of Medicine will be ready for its members. The optimists say in eighteen months, the pessimists place the shortest time at two years. The Academy has 40,000 volumes, and is the second medical library in the United States, the largest being the Library of the Surgeon-General at Washington. There will be space in the new building for 200,000 volumes. The Academy did at one time entirely depend upon donations, but of late it has bought nearly all its books. The Societies and the Sections of the Academy meeting at the Academy, at present, are the Medico-Chirurgical Society of German Physicians, the Surgical Section, the Section on Ophthalmology, the New York County Medical Society, the Neurological Society, the First District Dental Society, the Section on Practice, the Odontological Society, the Section on Laryngology, the Physicians Mutual Aid Society, the New York Surgical Society, the Section on Pediatrics, the Society of Medical Jurisprudence, the New York Academy of Medicine, the Section on Obstetrics, the Section on Public Health, the Neurological Section, the Section on Orthopedics, and the Therapeutical Section.

All papers in competition for the annual prize of $100 offered by the Medical Society of the County of New York, to be written by members of that Society, must be submitted by October 1, at the latest.

New York has a night medical service, which provides free attendance to all who apply at the police stations for it. A number of physicians are on the list at each station, to whom the applicants are referred, and who receive $3 per visit from the city for their services. The scheme is due to Dr. Nachtel, who originated it and had it adopted, through the assistance of the N. Y. *Times*. At first the calls were frequent; but as the newspapers ceased to discuss the matter, it seems to have passed out of mind; and now but few calls are made upon the stations. We would like to see the same plan instituted in each of our great cities. Too often the burden of attending such cases falls, most unfairly, on the physicians, who are called up from their beds to attend such persons, without any recompense. Every physician does in his ordinary practice an amount of charity, which, in proportion to his means, greatly exceeds the benefactions of a Child or a Vanderbilt. He should not be expected to perform a duty for which the city should provide.

Medical Journalism.—A great deal of activity towards centralization has been lately apparent in the circles of medical journalists in other countries than our own. For example, the French medical journals have formed a Medical Press Association, with the object of the protection of their own interests. In the United States also a similar movement has been taking place. The Philadelphia *Medical Times*, the *Dietetic Gazette*, and the *Medical Register* have amalgamated, and these in combination are published as one journal, The Times and Register, by the Medical Press Company. America is a large country and England is a small one, and hence no such scheme of amalgamation is possible, nor by any means desirable, as far as the journals devoted to medical topics in this country are concerned. In some respects our neighbors' example in this matter on the continent and in America might be worth adopting, but we should not be very much disposed to make the experiment.—*Med. Press and Cir.*

Discovery of an Assyrian Library Three Thousand Five Hundred Years Old.—The Victoria Institute held its annual meeting, before a large audience, at Adelphi Terrace, July 1st, Capt. Francis Petrie, the honorary secretary, read the annual report, which showed that there were now more than 1300 members of the Institute. A most interesting paper by Prof. Sayce was the feature of the occasion. It was chiefly an account of ceriain Babylonian discoveries tnat have lately been made, which show that fifteen centuries before our era there was an active literary intercourse going on throughout the civilized world of Western Asia, chiefly by means of the Babylonian language and script. Great libraries were collected formed of clay tablets, with cuneiform inscriptions. The archives discovered treat mainly of the conquests of Amenophis III., also throwing much light on the contemporaneous history of adjacent countries. Prof. Sayce hopes that there may yet be found in the sands of Syria and Palestine more of these treasures of such priceless value to our knowledge of those times.

FATHER FIELD, of St. Clements, pays the following tribute to the Red Cross workers at Johnstown: "There are a large number of persons sick and requiring medical treatment. The Red Cross Hospital, of the Philadelphia Branch of the Red Cross, is doing splendid work. Their camp hospital is a picture of neatness and order. The doctors are kept busily employed in attending to dispensary patients and those in tents. They need more mattresses. It is acknowledged on all sides here that the Red Cross, under the management of Miss Clara Barton and the medical staff from Philadelphia, are doing the real charitable work. Money sent to them will not be wasted or misapplied."

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 30, 1889, to August 5, 1889.

SEITH, ANDREW K,, Colonel and Surgeon. Is granted seven days leave of absence, by the direction of the Acting Secretary of War. Par. 12, S. O. 178, A. G. O., August 3, 1889.

HALL, WILLIAM R., Captain and Assistant-Surgeon. Is granted ten days leave of absence. Par. 3, S. O. 80, Headquarters Department of Dakota, July 27, 1889.

ROBINSON, SAMUEL Q., Captain and Assistant-Surgeon. The leave of absence granted for two weeks, by par. 11, S. O. 165, from these headquarters, is hereby extended ten days. Par. 8, S. O. 172, Headquarters Division of the Atlantic, July 30, 1889.

MAUS, LOUIS M., Captain and Assistant-Surgeon. Is hereby granted leave of absence on surgeon's certificate of disability. Par. 2, S. O. 173, Headquarters Division of the Atlantic, August 1, 1889.

By direction of the Secretary of War, so much of paragragh 1, S. O. 159, July 21, 1889, A. G. O., as directs Captain LOUIS BRECHEMIN, Assistant-Surgeon, to return to his station at the close of the encampment of the Illinois National Guards is amended to direct him to report in person not later than August 20, 1889, at Fort Robinson, Neb., for duty at that place. S. O. 174, Headquarters of the Army, A. G. O., Washington, July 30, 1889.

HARRIS, H. S. T., First Lieutenant. The leave of absence granted in S. O. 140, A. G. O., June 18, is further extended two months.

Changes in the Medical Corps of the United States Navy for the week ending August 3, 1889.

BRYANT, P. H., Assistant-Surgeon. Ordered to temporary duty on iron-clads, Richmond, Va.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service for the two weeks ending August 3, 1889.

HUTTON, H. H., Surgeon. When relieved at Mobile, Ala., to assume command of the Service at Baltimore, Md., July. 23, 1889

PURVIANCE, GEORGE, Surgeon. When relieved at Baltimore, Md., to assume command of the Service at Philadelphia, Pa., July 24, 1889.

GASSAWAY, J. M., Surgeon. Ordered to New Orleans, La., for temporary duty, August 2, 1889.

GOLDSBOROUGH, C. B., Surgeon. Granted leave of absence for thirty days, July 29, 1889.

VAUGHAN, C. B., Assistant-Surgeon. Orders to Norfolk, Va., revoked, to proceed to Cario, Ill., for temporary duty, August 1, 1889.

GROENEVELT, J. F., Assistant-Surgeon. Relieved from duty at Gulf Quarantine Station; order to Mobile, Ala., for temporary duty, August 3, 1889.

The Ins and Outs of a Dilemma.

THE "INS" of the Infant Food Dilemma are the parties who are at present trying to imitate

Nestle's Milk Food for Infants.

The "OUTS" are the clear-headed and well-read practitioners, who have used Nestlé's Food for many years, and know that when Cholera Infantum begins its savage onslaught on infant life in our large cities, Nestlé's Food is alone to be prescribed.

These men are in NO DILEMMA; they prescribe Nestlé's Food from June to September. As the present summer will probably be a very hot one, make a note of above. Samples sent on application to

THOMAS LEEMING & CO.,

(Please mention The Times and Register.) 18 College Place, New York.

PHLEBITIS.

BY A. R. SMART, M.D.,

Professor of Physiology, Northwestern Ohio Medical College, Toledo, O., Vice-President Toledo Medical Society; Corresponding Member Detroit Academy of Medicine, etc.

BY the term phlebitis we understand inflammation in the wall of a vein; the structure of a vein like that of arteries, is made up of three layers composing the vessel wall:

1. An outer layer of areolar tissue, with a little muscular fibre a little thicker, but otherwise resembling the tunica adventitia of arteries.

2. A middle coat of fibrous tissue (yellow and white) with muscular fibre, similar to the middle coat of an artery, but with a larger proportion of the former and less of the latter.

3. The tunica intima, a layer of endothelial tissue, consisting of a single layer of pavement epithelium on a structureless basement membrane, in the smallest veins, only the external and internal coats are found.

The tunica intima is not a vascular structure, and depends for its nutrition upon the outer coats. John Hunter, in 1784, defined phlebitis as applying to all the layers composing the wall of a vein. This we know is incorrect, the intima is not the seat of a true inflammatory process; does not exude lymph and form pus as do serous membranes; the walls of veins have little tendency to inflammation, but when found it occurs in the outer and middle coat. Under these circumstances, the intima will become clouded, rough, and eroded. Denuding a limited section of a vein, by detaching the tunica adventitia will produce this effect upon a corresponding section of the intima; this results from the interference with nutrition by cutting off its vascular supply. Smith says that the intima is liable to but one acute process, viz., an erosion or crumbling away of its structure from disease in the outer coats of the vessel. The intima has a perfectly smooth, glistening surface, and exerts an influence, not perfectly understood, on the integrity of the blood; the intima, too, is somewhat dependent on the condition of the blood and its movement. To maintain a normal condition of the vessel wall and of the blood, a current of healthy blood must be constantly passing along the surface of the intima, the vital activities of either being impaired by disorder in either. Quain says, so long as blood remains fluid it does not cause change in the vessel wall. To this statement we take exception; the condition of the blood in alcoholism, nephritis, syphilis, lead poisoning, etc., is known to cause disease in the intima of arteries, independent of clot formation. In syphilis and interstitial nephritis, endarteritis obliterans is not infrequent as a result of blood state, especially in the cerebral vessels. Why may it not similarly affect veins? There are conditions of the blood, the nature of which we do not understand, that cause pathological changes in the intima of vessels.

Phlebitis may be divided into two classes, depending upon the nature and source of the exciting cause. If from without the vessel, we find external

or peri-phlebitis. If from causes operating from within the vessel, internal phlebitis or endo-phlebitis. Smith, in "Pepper's System of Medicine," makes three forms of idiopathic phlebitis:

1. Simple or primary inflammation of the vessel wall.

2. The phlebitis arising as a part of inflammation of surrounding structures and involving the vein by contiguity of surface.

3. That arising from blood states. Practically, the conditions may be reduced to two—viz., those inflammations of the vessel wall arising from contiguity to diseased structures and those arising from clot or other foreign matter in the blood current, and from morbid states of the blood. It is not denied that the tissues composing the outer and middle wall of a vein may be the seat of primary inflammation; but aside from traumatic causes it is very rare. First, of what we may term peri-phlebitis. This type of inflammation in the wall of a vein may arise from cellulitis, erysipelas, injuries to wall of vein, amputations, or operations in general, involving veins and fracture of bones. In some instances it originates in the viscera, as in the liver and portal vein, and in the uterus after labor. It is specially liable to occur in the sinuses of the brain in connection with scalp or skull injuries, with chronic internal otitis, and with erysipelas about the face and head, particularly facial anthrax. This form of phlebitis may be associated with thrombosis or not, according to its extent and character. In the majority of cases a thrombus forms; but in some instances the inflammatory process in the outer and middle wall of the vein does not involve the intima. If only a portion of the circumference is the seat of disease, there may be swelling and partial occlusion of the lumen of the vein; yet if the intima retain its integrity, no thrombus will form, the inflammatory process may be fibrous (or adhesive), or suppurative. In the first instance, there will be increase in the connective tissue, and thickening of the wall of the vein from interstitial inflammation, but no clot will be formed. Loomis says this is the only form of phlebitis in which no thrombus occurs; the course of adhesive phlebitis is slower, and the symptoms less active than in the suppurative type. Pus may form between the outer coats of the vessel, which will from the crumbling away of the intima, enter the blood current, unless prevented by the formation of a thrombus. Sometimes the thrombus disintegrates, and the débris, with pus mixed with it, floats off in the circulation to set up foci of inflammation in distant parts; this constitues the most dangerous form of phlebitis—viz., the suppurative. Again, the adhesive and the suppurative types may occur together, the adhesive non-suppurative inflammation not unfrequently, by blending with the clot formed in the lumen of the vein, obliterates it, reducing the vein to a mere fibrous cord. This process, occurring on either side of a suppuration, inflammation would exert a salutary influence and prevent general dissemination of disease products. Suppurative phlebitis is by far the most dangerous form, because of the greater severity of the symptoms, and because of the tendency of the thrombus, which always forms, to disintegrate and wash out into the general circulation; this is the type usually, or at least frequently, occurring in cellulitis, erysipelas, and anthrax. It is found not unfrequently in the uterine and ovarian veins in connection with diseases of the puerperal state. When it occurs in the course of these disorders, it may not display any distinctive feature, but develops in a most insiduous and dangerous fashion.

The second general classification in which the inflammation or tissue change in the vessel wall is secondary to conditions of the blood itself are much the more common. By far the most frequent cause of phlebitis is thrombosis. Thrombosis has no essential connection with inflammation in the vessel wall, and in the majority of instances of clot formation there is no inflammation. Phlebitis is, however, often secondary to thrombosis. Thrombi may occur in arteries where they are commonly the result of disease of the intima. Thrombosis is much more frequent in veins, and most often is not dependent upon the state of the vessel wall; this is so common that Virchow proposed to abandon the term phlebitis and substitute "thrombosis." Again, he says the disorder known as suppurative phlebitis is not an inflammatory disease, but is wholly the history of a thrombus. In the type of phlebitis in question, the changes in the vessel are secondary to the occurrence of thrombosis. As already stated a thrombus is the result, nearly without exception, of antecedent disease in the vessel wall; so that, either as a cause or as a result, we find a thrombus an important factor in all types of phlebitis. The term thrombosis comes from a Greek word, meaning clot. It is applied to formation of a clot in the living blood- or lymph-vessels at some given localized point. It may occur in arteries, veins, or in the lymphatics.

In arteries the conditions of clot formation do not so much concern us in the present review; except to say that the condition of the vessel wall is a much more frequent factor of thrombosis than in veins. The blood, under certain conditions, has a tendency toward spontaneous coagulation in the veins. What are these conditions? First, let us consider the nature of thrombus or clot formation. Fibrin which composes the bulk of the thrombus does not exist preformed in the blood, it is formed from its antecedents under certain conditions. These genetic principles are fibrinogen, existing in the blood plasma. Paraglobulin or fibrinoplasten, supposed to come from the corpuscular elements. A third factor of the nature of a ferment, whose habitat is not definitely settled, is supposed to exist. The more recent views make the hæmatoblasts or blood plaques play an important part in formation of clot. Experiments seem to show that the white blood corpuscles and the blood plaques are each important elements in the process. Wooldridge has shown that the amount of fibrin formed exactly equalled the amount of leucocytes lost, determined by weight. It is thought by some that the ferment resides in the vessel wall and is set free at the moment the intima loses its normal vitality. By others that the ferment resides in the blood plaques, and is freed by their destruction and disintegration.

These elements, variously known as third corpuscles, hæmatoblasts, blood plaques, and other names are shown by Osler to be very important in the formation of fibrin. Nature closes a wounded vessel by the formation of a thrombus, the blood plaques are the elements which are first to settle upon the edge of the wounded vessel. The origin or destiny of these bodies is as yet involved in mystery, but it is safe to say they play an important part in coagulation, they are found relatively increased in all chronic cachectic or exhausting diseases, and in fevers in the later stages. It is in just these conditions that an increased tendency to spontaneous coagulation and thrombosis is found. These bodies, if the blood current is moving at a normal pace, keep in the center with the red corpuscles. If the movement becomes slow and stagnant, they collect with the leucocytes along the wall of the vein, where they tend to adhere. The plasma is a living fluid and while in motion resists coagulation, in this being aided by some influence exerted by the intima. Both the blood and intima depend upon the free and constant change in the blood current for their integrity; blood corpuscles broken down and disintegrated, or leucocytes from lymph glands as practised by Wooldridge, will not, when injected into the bloodvessels of a healthy animal, induce coagulation. It is only plasma which is tending toward necrotic change that is prone to coagulation. Space forbids more minute inquiry into this part of the subject, but from what is known we may safely assert, that the formation of fibrin is a result of necrobiotic change in the blood, that the factors exist in the plasma and in the colorless and so-called third corpuscles, or blood plaques, that they are freed and fibrin formed under conditions that change the normal activity and constitution of the blood or its relations to the vessel wall. Under what conditions is spontaneous coagulation prone to occur? When we consider that the most frequent cause of phlebitis is a primary thrombosis, that in a majority of cases there is no inflammation of the vessel wall, prior to the thrombus, it becomes an important question to note the diseased states in which thrombosis may be likely to occur. Delafield says, "the peculiar state of the blood causes vaginal and vulvar thrombi," also "thrombosis of large veins without inflammation or other facts in general condition to account for it, is not an uncommon occurrence." It is most often found in elderly people and in the femoral or the veins of the neck. Charcot says that the blood in old age has a smaller proportion of red corpuscles and coagulates more readily. Obviously any cause which increases the proportion of fibrin factors in the blood, will increase the tendency to coagulation. In rheumatic fever, scarlet fever, diphtheria, inflammatory croup, pneumonia, pregnancy, malarial, typhoid and typhus fevers, after severe hemorrhages, phthisis, cancer, the various cachexiæ and wasting diseases generally, all these states induce, in greater or less degree, this condition of the blood. It is not true that so-called sthenic or inflammatory conditions alone produce hyperinosis and inopexia; any cause that lowers the nutrition of the system is productive of such results. The fibrin factors are a lower grade of elaborated product, and their excess means impaired nutrition. Thrombosis occurring either slowly or rapidly in arteries or veins, but most in veins, is by no means uncommon. Cases of sudden death from alleged heart failure in croup, diphtheria, are often, no doubt, thrombosis of the right breast or pulmonary artery. It is believed by Tanner and with him many eminent clinicians, that central thrombosis, is much more frequently a cause of death in croup and diphtheria than asphyxia, and the same may be said of pneumonia. The thrombus may form in some of the peripheral veins and becoming dislodged, be washed into the right breast or pulmonary artery. This is specially true in puerperal cases. Central thrombosis is not so common as other forms, but is found most in septic condition of the blood, in parturient states, and the exhaustion and debility consequent to fevers, hemorrhages, etc. Barker says, embolism and thrombosis of the right heart and pulmonary artery are more common in puerperal women than arterial thrombosis. It is more frequent also in primiparæ. Virchow thought thrombosis of the pulmonary artery was always secondary; it is certain, however, that it may not be embolic but primary. The blood in cancer, phthisis, and the cachectic states in general is liable, especially if stagnated, to form clot and set up phlebitis or to originate emboli and thrombosis of distant parts. Rheumatic fever induces a blood state which favors thrombosis; the thrombus is most apt to form at the junction of the deep and superficial veins; according to Paget, the vein may be partially or completely filled by the thrombus, the œdema and pain varying accordingly. Paget mentions a form of phlebitis occurring in gouty subjects, which he calls adhesive; it is associated with thrombi, is most common in the superficial veins, and may entirely obliterate their calibre. The plastic deposit in these cases extends inward from the wall of the vein, and may extend a long distance, obliterating large veins, even the vena cava; it occurs sometimes in connection with thrombi that are disposed to suppuration and disintegration. They thus limit the diseased process and cut off from contamination the general circulation. This organization of thrombi is much more frequent in arteries, but occurs in veins. Malarial fevers exert an influence on the vascular glands which lessens the red corpuscles and increases the white corpuscles and the pigment. With this state of the blood and a weak heart, clot formation is probable. The excess of pigment coming mainly from the disintegration of the red corpuscles causes embolic accumulation and capillary thrombosis. Thrombi under these conditions, if the heart is weak, are likely to form in the veins. We are led to infer as we consider this subject, that venous thrombosis, both central and peripheral, is a frequent and often unsuspected factor in the history of the later stages of fever. In the thrombosis of peripheral veins the state of the blood plays the more important role. Cardiac weakness, usually present in such cases, is more potent in determining venous than arterial thrombosis. Thrombosis following fever is most apt to occur in the left femoral vein. The reason is found in its course and

relations; it is longer, more oblique, and lies under the right common iliac artery in the upper part of its course, and is also subject to rectal pressure. The left femoral vein is also most often the seat of thrombosis in rheumatic phlebitis. In all these cases the femoral popliteal and saphenous veins are most frequently involved, but the radial and brachial may be. Thrombosis of axillary vein is rare. Thrombosis in the peripheral veins is more liable to occur near valves than elsewhere. The thrombus is more apt to disintegrate and give rise to emboli, if near a junction with another vein.

Thrombosis is entirely distinct from embolism, yet embolism is often a sequence of thrombosis. Dr. Fagge records a puerperal case that had had phlegmasia alba dolens, and she was suddenly seized with abdominal pain, collapse and death. No tympanitis occurred; at the autopsy the heart was found healthy, and a thrombus or, more correctly, an embolus had plugged the mesenteric vein; the portion of the intestine corresponding was discolored and in incipient gangrene. Stokes reports a case of femoral phlebitis following typhoid fever; patient was up and about the ward, when he was suddenly seized with intense pain in the splenic region, with elevated temperature, followed by symptoms indicating general phlebitis. The autopsy showed occlusion of the pulmonary artery. In the later stages of fever and in puerperal states, pain in the hip, or deeply seated in the calf, is indicative of mischief in the veins, and should lead to a suspicion of thrombosis, which may ultimately extend upward or give rise to emboli. It is asserted by Lidell, Trousseau, Druitt and others, that the so-called metastases of rheumatic fever are of this character. Tanner calls attention to the so-called cerebral metastasis occuring suddenly in some cases of rheumatic fever, and suggests that the stupor, embarrassed respiration, etc., seen in that condition, probably result from embolism of the pulmonary artery or from thrombosis in the right cavities of the heart.

Atlee reports a case of thrombosis of the femoral artery ending in gangrene of the extremity, which followed unusual exertion; the femoral obstruction was preceded by signs of cerebral thrombosis. In another instance phlebitis of the popliteal vein was found after over-exertion and exposure. In one of the daily papers of recent date I find the following: A young lady, of 19 years, never sick in her life, did a large washing on Monday—presumably over exerted. On Tuesday morning, shortly after breakfast, was seized with pain in her foot, in three hours the pain had gone to her heart and she was dead.

Diagnosis.—Neuralgia of the heart. Was it correct? Fidy in reviewing the causes of sudden death says: "Embolism of the right heart or pulmonary artery may cause death very suddenly; the clot may be detached from the saphena or femoral by very slight causes and swept along to the heart." Was not the pain in the foot caused by thrombosis in the veins of the leg at some point, the thrombus being subsequently detached, possibly by the frictions, etc., made to relieve the pain, and swept along to the heart, a much more probable conclusion than that neuralgia should destroy life in a young person with a perfectly sound heart. Nièmeyer cites cases where clots from the femoral vein washed into circulation and occluded the pulmonary artery causing death, also cases of pleurisy with the same results. Frictions in phlebitis or phlegmasia of the periphery are to be avoided because of the danger of dislodging clots and washing them into the general circulation; the same danger would follow active exertion. Weak heart and low tension in the bloodvessels is a prominent feature in the causes of thrombosis. In marasmic cachectic conditions, not only is the heart weak, but the capacity of the vessels exceeds the volume of blood, and a slow current results; this is an element of danger after hemorrhage and long fevers; it often happens if the dangers from thrombosis can be averted in exhausting diseases, the crisis may be passed in safety. Henoch reports a case of scarlet fever in a boy of 7, in which the vena cava inf, was converted into a solid fibrous cord by a thrombus extending upward from the iliac and peripheral veins. It was thought to be a marantic clot due to cardiac weakness. When a thrombus forms from the feebleness of the circulation, or from the state of the blood, it behaves differently than when it forms from disease or injury to the vessel wall. In cases of injury to the vessel wall, as in ligation or thrombus from local lesion of veins, the thrombus organizes, 1st, by a growth of granulation tissue in place of the endothelium; 2d, by the pushing forward into the thrombus of vascular supply from the outer coat of the vein. Thrombi under these conditions do not extend beyond the junction of the first branch in the vessel. While in the spontaneous coagulation and formation of thrombi with secondary involvement of vessel wall the thrombus may extend indefinitely.

Phlebitis and thrombosis of the vessels about the cranium are a common and important class of diseased vein conditions. Meigs reports a case of cerebral thrombosis in a young and previously healthy woman, caused by long continued mental anxiety. Thrombosis of the cerebral sinuses from other blows or injuries to the cranial vault is common; cerebral thrombosis often happens when the vessel wall is healthy, caused by the state of the blood, or feeble circulation, or both. Coagulation is often extensive under these circumstances. It is not infrequent after protracted bowel diseases of infants, and, no doubt, constitutes the condition many times known as brain complication, when the malady "goes to the head" and speedily snuffs out the little sufferer. Henoch says thrombosis of the cerebral veins is frequent in the exhausting diseases of childhood and infancy. Lidell says there are four localities where the blood is prone to coagulate in debility, viz.: the cavities of the right heart, veins of the pelvis and lower extremities, and sinuses of the dura mater. Inflammation or periphlebitis in the venous sinuses of the brain is a common event in connection with many diseases about the head and face. Lesions of the scalp, of the skull, or of the membranes of the brain often give rise to it. Scarlatina and erysipelas of the face and scalp are specially prone to originate it. Otitis usually sets up cerebral phlebitis through the medium of caries in the temporal bone. Pyæmia

may thus occur. Suppurative phlebitis arising in this manner may cause pyæmia, constituting an instance where pyæmia may exist without external evidences. In that exceeding fatal disease, facial anthrax, and in lesions of the nasal fossæ, thrombosis of the facial, frontal, or temporal, or of the ophthalmic veins, may extend to the sinuses of the dura mater and to the veins of the diploe. Marasmic or non-inflammatory thrombosis is not uncommon in elderly people, or after free venesection or hemorrhages, and, as noticed, in children after exhausting diseases. The uterine sinuses and ovarian veins are often the seat of thrombi, which may soften and give rise to pyæmic abscesses in distant parts. This is most common after labor or abortions. The thrombus in these instances may arise from the entrance of septic material into the uterine veins, or from periphlebitis of the uterine or ovarian veins communicated by inflammation in the walls of the uterus or in the cellular tissue of the broad ligaments. Dr. Putnam-Jacobi found phlebitis with thrombi in the post-vaginal veins leading to the uterine sinuses. The lymphatics may be the seat of thrombosis, most common in the lower extremities and in puerperal states, and known as phlegmasia alba dolens. It is probable the condition rarely exists alone, but is connective with phlebitis. It may occur in the upper extremities, and is not infrequent after fevers. In phlegmasia following typhoid fever the pain and swelling are greatest over the femoral vein. Stokes says the diseased process is identical with that which occurs in parturient women. Occurring as a sequel, or in the later stages of fever, it is not always painful, and in any case the pain may be localized in a toe, or in the foot, or in the sciatic notch. Trousseau thinks the principle features of phlegmasia, the venous thrombosis and secondary phlebitis, the enteric irritation in fever, and the uterine irritation acting as an exciting cause in either form, phlegmasia, is also a frequent and sometimes the only prominent sign of deep-seated visceral cancer, indicating its existence when no tumor can be felt. In all these cases the blood condition, the feeble circulation and sometimes pressure on the veins in the cavities of the body, are the determining causes. Compression of a vein causes thrombus. Some surgeons consider thrombosis and phlebitis as not uncommon results of surgical pressure on aneurisms during amputations, etc. It is probable that phlebitis is not uncommon in the visceral vein. In obstructive disease of the liver, cirrhosis, etc., it has been observed that the œdema of the subcutaneous tissues of the abdomen was not dependent on the liver disease, but on phlebitis and obstruction of the vena cava ascendans. In cases where meteorisms and ascites were present without œdema, no disease of the vessel wall was found. The portal vein and its branches are the seat of thrombi, we believe, much more frequently than suspected. The suppurative form, or pyle-phlebitis, is induced by malarial and septic poisoning or visceral disease, also by hemorrhoidal inflammation, dysentery, or other localized inflammation of intestinal tract. The chronic form of portal phlebitis will present symptoms almost identical with cirrhosis of the liver; the acute suppurative form has no bloating of abdomen or acetic collection, but is accompanied with chills, sweats, diarrhœa, and phenomena like that of pyæmia. It would be interesting to discuss the relations of phlebitis to pyæmia, also to review the treatment of these conditions, but space forbids, and we will only say that in the treatment of thrombosis in general, and especially in those forms occurring in connection with scarlatina, diphtheria, rheumatism, and other forms, carb. of ammonia will be found useful because of its power to lessen coagulation and to stimulate the action of the heart, two very important factors in these conditions.

THE NASAL CAVITIES.

(Read before the Southern Kansas Medical Society.)

By E. E. HAMILTON, M.D.,
WICHITA, KANSAS.

THERE is no mucous surface, of equal extent, in the body, the functions of which are more important than those of the nasal cavities.

Standing at the gateway of the respiratory system, exposed as no other mucous surface is to our climatic changes, characterized by excessive humidity to-day, and almost absolute dryness of the atmosphere to-morrow; is it to be wondered a surface so exposed, having to meet not only daily but often momentary changes in the humidity of the inspired air should easily become impaired in function.

Such an impairment, besides its attendant local discomfort, too often produces grave effects upon neighboring organs and through them upon the general body economy.

Briefly let us notice some of their most important anatomical points as a basis for an intelligent understanding of their uses in helping to maintain our existence.

In describing the nasal cavities we include the vault of the pharynx for reasons more physiological and pathological than anatomical. Above the border of the soft palate the pharynx, like the anterior nasal cavities, is respiratory in function, being traversed, practically, by air alone. Below this boundary line, besides being a channel for air in respiration, the pharynx is impinged upon by food and drink, and is, therefore, kept comparatively clean.

In the upper region mucus and cast-off epithelial cells tend to adhere to the sinous surfaces, particularly if, as the result of morbid conditions, the glands or cilia of this region are destroyed. We then have the one posterior and the two anterior nasal cavities, the boundary line between which is the posterior nares and the anterior limit of the pharyngeal vault.

The septum, which forms the inner wall and separates the anterior nasal cavities, is seldom perfectly perpendicular, its center usually deviating to one side, oftener the left, encroaching more or less upon the corresponding cavity, narrowing its calibre and sometimes obstructing the breathing.

The outer wall of each cavity is traversed anteroposteriorly by the three scroll-like, turbinated bones, which serve to increase the mucous surface and divide each passage into three incomplete supplementary passages or meatus.

The two upper meatus are connected by canals with three accessory cavities, the sphenoidal, maxillary and frontal, the former of which opens into the superior, the two latter into the middle meatus. The lower meatus has the opening of the nasal duct which often becomes involved in the same catarrhal process to which the nose is subject.

These accessory sinuses do not form a part of the nasal cavities proper, but are sometimes, though by no means as often as has been generally supposed, affected as a complication of nasal catarrh.

They probably serve as reservoirs for warm and moist air, thus aiding the respiratory function, but their chief use is undoubtedly to give lightness to the bony structures of the face.

The mucous lining of the cavities may be divided according to function and microscopic character into two portions, viz., a superior or olfactory, and an inferior or respiratory. The former includes the covering of the upper third of the septum and the superior and upper third of the middle turbinated bones. The respiratory portion being the part below these limits.

In contrast with the respiratory the membrane of the olfactory region is thinner and more closely adherent to the periosteum, contains fewer glands and is covered with non-ciliated tesselated epithelium. It is the part to which the olfactory nerve is distributed, the substance of the membrane being largely made up of terminal filaments of that nerve. This region presides over the sense of smell, the proper enjoyment of which function requires that no mechanical impediment, such as polypi, hypertrophies, etc., shall prevent the admission of odors, particularly over the inferior turbinated bones.

This thickening is due partly to a grouping of follicular glands in this vicinity, but more to a plexus of bloodvessels—a cavernous network of veins giving the parts somewhat the character of erectile tissue. The nerve supply of this region comes mainly from the nasal branch of the ophthalmic and from branches of the spheno-palatine ganglion. This region has a connecting link with the sympathetic system through the vidian of the spheno-palatine ganglion, and through the first division of the fifth with the ciliary ganglion particles to the sentient surfaces; that the glands and nerve filaments should be healthy; that the membrane should be moist and not clogged with unhealthy mucus, and that the nerve itself should be unimpaired in function.

Minute particles of odorous matter are drawn into the nasal cavity with the inspired air, and lodging against the membrane are dissolved in its mucus, where their peculiar qualities are recognized by coming in contact with the terminal filaments of the olfactory nerve. In the respiratory region the mucous membrane is covered with columnar ciliated epithelium.

It is thicker in places. This connection is of importance, as it sheds light upon certain reflex neuroses of nasal origin. The posterior nasal cavity contains two important anatomical points, viz: The Eustachian tube openings and the pharyngeal or Luscha's tonsil. The former are trumpet-shaped openings directed toward the posterior nares situated in the superior and lateral wall of the space just above the level of the floor of the nostrils. The latter is an aggregation of glands situated at the superior and posterior part of the space, and so called from their resemblance to the faucial tonsils. The most important function of the nasal cavities is its respiratory function. They are the natural channels for the passage of air to the lungs in respiration; to the larynx in phonation, and to the ear in audition. During the passage through the cavities the impaired air becomes filtered and cleansed of impurities, and it becomes warmed and moistened. Dust and coarser particles are arrested by the coarse hairs or vibrasse which guard the entrance to the nostrils. Finer particles are caught by the moist ciliated mucous surface. The vibratile motion of the cilia being directed backwards, it is probable that the normal secretion of the nasal glands is carried to the pharyngeal or Luscha's tonsil and there reabsorbed. When the balance between secretion and its physiological removal by this backward ciliary motion is interfered with, as in acute catarrh, a discharge from the nose results.

Warmth is communicated to the air by the long and tortuous fossæ,—also by the admixture of a watery secretion coming from the underlying blood supply. The normal function of the mucous glands is to secrete enough mucus to keep the membrane moist and pliant, any excess of this is abnormal. Nasal mucus is composed of 92 or 93 per cent. water and 7 or 8 per cent. solid matter. Robbed of a small quantity of this water it becomes thick, inspissated and unhealthy. Every breath of inspired air must gain moisture, if not it would exert an injurious effect upon the membrane of the lower air-passages by robbing them of their moisture.

Physiologists estimate that from twelve to sixteen ounces of serum are poured out daily upon the surface of the nasal membrane, the object of which is to prevent the inspired air from robbing the lower air-passages of their scanty supply of mucus.

We find in this plexus of bloodvessels under the turbinated bones the apparatus which supplies this water. The watery constituents of the bloodvessels in this situation exude from the vessels through the membrane and appear on the surface to be taken up by the inspired air. The vaso-motor system of nerves controls this function regulating the supply according to the demand. In health this control is so delicately exercised, that this exosmosis of serum adapts itself to every existing atmospheric condition. The function of the nasal cavities as resonant chambers for the voice is an important one. The voice is formed in the larynx, but purity of voice depends upon these chambers being free.

We are all familiar with the nasal intonations resulting from the obstruction of these cavities by swellings, new growths, etc.

Many diseases in, or symptoms referable to other parts of the body, now have their recognized origin in the nasal cavities.

This subject is a large one and deserves much more attention than can be given it here. I would like

very briefly though to call you attention to a few troubles of mucous surfaces that are continuous with the nasal membrane which depend upon the nose as an etiological factor. These may occur: 1. By extension through continuity of structure. 2. By the irritating effect of catarrhal discharges. 3. By any morbid process that deprives the inspired air of its heat and moisture, or fails to rid it of impurities. 4. By reflex irritation. Under the first cause, extension through continuity of tissue, we may cite middle ear troubles as an example. As is well known, most inflammations of the tympanum start from the pharyngeal end of the Eustachian tube. This fact implies a pre-existing post-nasal trouble, and as the relative position of the parts does not permit gravitation of the discharges, it must result from an extension of the morbid process over the mucus surface involved by continuity of structure. Under the second cause, irritation of catarrhal discharges, we may cite particularly pharyngeal and laryngeal catarrhs. The source of the diseases may be in part due to an extension downward of the inflammatory process, but a far more frequent cause is a morbid secretion poured out from the nasal cavities above. This discharge adheres to the membrane interfering with its function, and causes a desire and effort to clear the throat of the offending matter. That the position of the larynx in normal respiration permits these discharges entering the laryngeal cavity is proven. That this cause does not operate to any great extent in the production of bronchial troubles is probable.

The larynx and trachea are both intolerant of any foreign matters, and usually reject these discharges before they reach the bronchi.

Anything that deprives the inspired air of heat and moisture, or fails to rid it of impurities is injurious. This condition may result directly through some local morbid process that destroys the cilia of the nasal membrane, or causes destruction of the glands, and absorption of the bloodvessels of the submucous tissue.

In these cases the cavities fail to perform the functions of preparing the air for entrance into the lungs.

Indirectly the same effect much oftener results from an enforced habit of mouth breathing, induced by some obstruction to nasal respiration. In either case the inspired air is not sufficiently warmed, moistened, and filtered to deprive it of its irritating qualities. As a consequence the membrane of the respiratory tract is robbed of its moisture, and irritated by contact of the cold unpurified air of inspiration, until finally a chronic inflammation is induced as a result.

Mouth breathing is a fruitful source of pharyngeal and laryngeal catarrhs. I am persuaded that bronchial troubles are often produced by the same cause, particularly in young children whose powers of resistance are not great.

In mouth breathers, the tendency is to swallow the food as quickly as possible in order to permit breathing. Indigestion results from the food being imperfectly masticated and insalivated.

Mouth breathers are usually dyspeptic, anæmic, and poorly nourished.

The moral is, establish free nasal respiration by removing enlarged tonsils, hypertrophies, or any condition causing nasal stenosis.

There are sensitive areas in the nasal mucous membrane, the stimulation of which through some local morbid process produces reflected phenomena, some of the most important of which are cough, laryngeal spasm, asthma, photophobia, lachrymation, headaches, facial neuralgia, etc. The production of these symptoms is probably favored by a neurotic habit either inherited or acquired. That complexity of symptoms, known as asthma, hay fever, etc., has for its predisposing cause, according to the best authority, a diseased condition of the nasal mucous membrane. Added to this a neuresthenic condition and we have the factors latent, which are awakened to action in a paroxysm by some extraneous irritant. Much evidence has accumulated to show that asthma has for its causation a neurotic habit, nasal disease, and some atmospheric condition—the nasal disorder being the most important.

Placing the nose in as healthy a condition as possible has been followed by very satisfactory results in the removal of these symptoms.

THE JUGULATION OF ACUTE DISEASES.

(Read before the Nebraska State Medical Society, at Kearney, Neb., June 22, 1889)

By L. A. MERRIAM, M.D.,
OMAHA, NEB.

THE word jugulation is derived from the Latin verb, *jugulare*, to strangle. In its full signification, it means not only to shorten the duration of the disease, but also to lessen the severity of the symptoms and prevent or mitigate the development of pathological lesions. A popular, but erroneous belief among the laity, and the majority of physicians, is that acute diseases have a natural period of continuance, notwithstanding the best efforts the scientific physician may put forth, and that the whole duty of the physician consists in alleviating suffering and conducting the disease to a safe termination, even though it may take weeks or months to do so. This idea, originating in ignorance, has been perpetuated by the dishonest physician, who, regarding the practice of medicine as a method of making money, prefers to extend the number of his visits, thereby increasing the size of his bill. The progress of scientific inquiry during the present century, and, especially, during the past twenty years, has demonstrated much concerning the nature of diseases, their prevention and appropriate treatment; yet how many physicians of to-day resort to methods of treatment long since proven to be erroneous, from a scientific basis, worse than useless, even positively detrimental to the best interests of the health and life of the patient. We gather in our State Medical Society the best educated and most skilful physicians of the State, and yet even here I shall find opponents to the progressive views I offer. Most of you will readily admit that there may be a few acute diseases which may be jugulated, or cut short in their early stages, before pathological lesions have been produced, and that some other diseases may be so jugulated that the pathological lesions will not be severe or exten-

sive, but you are not yet ready to admit that all or even many acute diseases can be thus successfully jugulated; nor are you ready to dispense with your old methods of poly-pharmacy, and accept the scientific treatment of to-day with pure medicines and definite doses. That the practice of medicine is becoming more precise, more accurate, more uniform, and more scientific is acknowledged by all studious, progressive physicians. That all acute diseases when placed under proper treatment in their early stages may be successfully jugulated I firmly believe. In all departments of nature, conditions mould fashion and determine all things. Life, health, disease and death depend upon conditions. Our duty then when called to treat disease is to remove all unfavorable conditions, and by appropriate therapeutic agents regulate the life forces of the body, so that the organs or tissues in process of degeneration may be restored to their normal condition and function. Compare, if you will, the recent methods of prevention, management and treatment of surgical fever, puerperal fever, typhoid and typhus fevers, measles, scarlet fever, smallpox, diphtheria, yellow fever, gonorrhœa and syphilis, generally known as germ diseases, and the methods of treatment in use less than twenty years ago. It is important to remember that a bad physiological condition is the principal accessory to the operation of the microbes, and while it is well to make a direct attack upon them with germicides, it is also very necessary to strengthen the organism against their influence by the use of the vital stimulants, chief among which stands strychnia and its salts. The value of cleanliness and corrosive chloride of mercury in surgical cases and the puerperal state is well known to you all, but the great value of the sulphide of calcium in measles, scarlet fever, diphtheria, smallpox, and yellow fever as an internal germ destroyer, has so long been demonstrated that no one who practices medicine need be ignorant of its virtue any longer. Take the long list of *pyrexias*, the result of various conditions, such as a sudden chilling of the body, etc. Some of these will be aborted naturally without medicine. Others will develop a condition which we call febrile, and by its continuance the malady becomes localized, and the affected organ undergoes alterations in structure. By suppressing the cause of these lesions, namely, the functional trouble which appeared at the commencement of the disorder, by controlling the fever which is the manifestation of this functional derangement, we control the disease and it is averted or jugulated. The jugulation of many acute diseases, when treated in the early stage, is often abrupt and complete. When treatment is begun at a later stage, and degenerative changes are well advanced, and pathological lesions well under way, the jugulation is less rapid, more time being necessary to restore the normal equilibrium. In some diseases jugulation becomes progressive in character, diminishing the severity of the symptoms and lessening the duration of the disease, and is a potent factor in preventing grave lesions, thereby forestalling the dangers that are sometimes found in convalescence. The proper method of treatment by which acute diseases may be successfully jugulated I shall proceed to show, basing my conclusions on actual cases in practice. Let it be remembered that I insist that the malady be treated early, before the organic lesions have become fixed. The difficulty at the first lies in the dynamic disturbances with which it commences, and the keen diagnostician can form an opinion from these without waiting for pathological results. The dynamic disturbances prolonged, will surely bring about some pathological lesion, and to turn about this morbid current, before great injury to some organ has been caused, is the duty of the scientific and skilful physician. Let it be remembered that medicines, like foods, act upon living matter by their material and dynamic properties, and they become valuable when they furnish the vital energy which is requisite for the restoration of the normal equilibrium. Hence the necessity of giving medicines that are pure and have a definite strength. This can only be done by using pure alkaloids, and other medicines that have a definite chemical combination. Discard all crude drugs, such as leaves, roots, tinctures, fluid and solid extracts, and by using pure medicines, adopt the dosimetric method, as laid down by its founder and great teacher, Prof. Ad. Burggraeve, of Ghent. What this dosimetric method is, and what are its fundamental principles, I shall proceed to show. The word dosimetric means measured doses, or the giving of pure medicines, with mathematical precision as to quantity and time. The medicaments should be administered just so far as to produce the desired effect, and in small doses, increased in proportion to the acuteness of the disease.

You will observe that in acute diseases the treatment is sharp and active. In chronic diseases the treatment is made to correspond to the character of the disease. These are the fundamental principles of dosimetry. But how, you may ask, can these granules of pure alkaloids jugulate disease. Take the initial fever of the pyrexias, which, if left to itself, persists with remittences of more or less duration or regularity, sometimes rising suddenly, and sometimes little by little, and under the influence of this fever, the condition of the patient becomes greatly aggravated, and finally the anatomical lesions appear in the organ which becomes the seat of the localization. Now, if it be true, as I claim, that by controlling the preliminary fever, and restoring the perverted functions, we prevent the localization of the malady, we have surely jugulated the disease. The agents most used to accomplish this work are aconitine, veratrine, digitaline, and strychnine, given together every thirty minutes, or every fifteen minutes, and in quantities suited to the case in question. I do not claim to be able to correct the deviations imparted to nutritive functions by the drathesis inherited from our ancestors, but I do claim that by the use of pure alkaloids and other medicines having a definite chemical composition we have the best and most scientific method of treatment at present discovered. Suppose you are called in the month of March, at 1 P.M., to see a man who had been exposed to a severe rain-storm, had become thoroughly wet on the night before, had a heavy chill at 9 o'clock in the morning, and you now

found him with a temperature of 102° F.; pulse 100; headache, backache, and a general feeling of malaise, with a severe pain in the region of the right nipple, some coughing, with a little expectoration of viscid, transparent mucus. On examination of the right lung you detect some engorgement. Shall you wait until you get the rusty sputa and crepitant râle before you decide that you have a case of pneumonitis. Three or four hours later you may have these symptoms, but your time for action is precious. At once give your patient one granule each of aconitine $\frac{1}{150}$ of a grain, digitaline $\frac{1}{67}$ of a grain, arseniate of strychnine $\frac{1}{134}$ of a grain, veratrine $\frac{1}{134}$ of a grain. Give one each of these granules every fifteen minutes. They are tasteless, small, easy, and pleasant to take, and in a few hours you will have the satisfaction of finding the pulse and temperature falling to nearly or quite normal, a profuse perspiration, a general feeling of comfort and absence of pain. Plenty of water should be given with these alkaloids as an adjuvant. The rusty sputa and crepitant râle may not appear, yet with these agents, even when they do appear, the pneumonitis may be quickly, safely, and completely jugulated.

It is said by my opponents that the defervescent alkaloids, such as aconitine and veratrine, are dangerous agents, and leave the patient in a state of great depression, hence they ought not to be used in ataxic and adynamic affections. In the hands of a bungler and ignorant physician, they, like the surgeon's knife and obstetric forceps, no doubt are dangerous. But in the hands the skilful they are agents of precision, and are indispensable. Let it be noted that asthenia is in these cases hidden behind sthenia, and when sthenia is brought down asthenia shows itself the more forcibly, the more violent the pyrexia has been.

Here, then, comes in the great value of digitaline and arseniate of strychnine in supporting the life forces of the body. Of the one hundred and more dosimetric granules now ready for use and used by many physicians, I have only, thus far, in this paper noted five, hence do not understand me to say that the jugulating of all acute diseases is done with these five agents. I have used the dosimetric method successfully in measles, scarlet fever, pneumonia, diphtheria, typhoid fever, and peritonitis, and have succeeded in jugulating these diseases far better than by the old methods of polypharmacy, and with greater satisfaction to my patrons.

Many of the alkaloids I have never used, because I have had to grow into the practice by degrees, but I have seen enough to convince me that it is a great improvement over the nauseating compounds of polypharmacy and crude drugs. And when I read of the cases in practice by other reputable physicians, I have from my own limited experience seen enough for me to believe their statements, and I shall continue to use more of the alkaloids, as I find myself able to apply them.

MERCK'S *Bulletin* for June contains a useful table of doses of the newer remedies; many of which have originated with this house.

DIPTHERIA.

(Abstract of a paper read before the Southern Kansas Medical Society.)

BY J. T. POTTER, M.D.

MY first treatment of this disease was in the autumn of 1875, when we had in the city where I was practicing in Eastern New York an epidemic of it of a very severe type, which generally developed rapidly, giving the characteristic mal-odor in a few hours. I concluded to give heroic treatment, and went at it with counter-irritation and strong topical applications, and I think this proved to be the most successful treatment it received in the city, and probably the hardest and most inhuman. As soon as I was sure that I had diphtheria to treat, I blistered deeply over the seat of the disease and always had bad sores, but as truly saw the corresponding improvement on the mucous membrane. In one dangerous case of a child of four years, where I was called in council, we gave chloroform to make our treatment more humane, and applied the hot hammer to get our blister, and saw a marked improvement in an hour, and a rapid recovery. I still thought this metastasis treatment too severe, and studied earnestly to find some agent that would take the place of it and be as sure of doing good. I believe I found the therapy sought in the bichloride of mercury. This I used for one year, and thence changed my treatment to the mild chloride, which I have since used. Now I give calomel in small doses oft repeated, not for the cathartic effect, but simply to cause the whole glandular system to discharge freely.

As a topical application I use a strong solution of the nitrate of silver. As a milder wash or gargle, and one which I pass through the nose if necessary, I use the perchloride of iron, glycerin and water, in the proportion of one part each of the former to six or eight parts of the latter. If the disease has developed extensively in the nose, I use this two or three times a day. If the sloughing is deep and severe hemorrhage follows, I use the above wash double this strength until the trouble is checked. Powdered pepsin is put on the patches every hour or two until they come off. Dover's powder is given in the early stage of the disease, but not, as a rule, after the angina is troublesome. I exhibit one large dose of quinine in the earliest stage of the disease, and one dose each day for four or five days, each being a little smaller than the preceeding. One great point in the treatment is proper nourishment. From the decline of the inflammatory stage I pay as much attention to this as to medicaments, and give it as regularly, and give as explicit direction in regard to its administration. And if I fail of administration, per oram, I give it per anum. If rectal alimentation must be resorted to I use, with the nourishment, a small quantity of opium to allay the irritation and assist nature in its retention. I find no tonic in the stage of convalescence to be as good as some preparation of cinchona and iron, my pet prescription being—elix. calisaya, iron and strychnine.

My treatment has never failed to bring my patients through, and many of my brethren are using it with the same success.

THE MEDICAL PRESS COMPANY, LIMITED.

IT seems that the aim and scope of this Association are not yet so fully comprehended as we believed them to be. The publication of the articles of partnership of the Medical Press Company, Limited, will inform any one who is interested as to the personnel of the Company which owns and controls THE TIMES AND REGISTER. This has been on record for months, and as there is nothing to be made a secret of, no measures have been taken to keep it secret. If we have not published this information previously, it was simply that we did not believe any one cared to know it. The objects of our company are perfectly well defined, and are open to the light of day. We have no hidden interests, no deep-laid schemes of treachery profound, with which to "envelop in slimy embrace[1] every legitimate interest of scientific medicine." We are not a "wolf in sheep's clothing;" though we confess, reluctantly, that we do wear woolens in cold weather. Whether we are a "hydra-headed monster" may be judged by a glance at the genial countenance of our president, Professor Pancoast.

Of the members of our company, it will be seen that three are physicians in active practice, one is a railroad magnate, and the others give their time and attention to the business interests of the Company, here and in New York.

We are not, up to the time of going to press, patent medicine men or manufacturers; we haven't leagued together to break down the medical journals by withdrawing our advertising from them, because we haven't any to withdraw. We haven't any club of any kind, to wield upon the heads of any journals which we want to gobble up at a bankrupt price, and we are not the sort of men who do such things. We haven't had the experience in blackmailing and bulldozing necessary to enable us to form such a scheme, and if we had, we think we have too much good sense to put it into operation.

To the other medical journals our attitude is simply this: When a periodical is well established fulfilling a need, with interests which require a journal to represent them, and an income which warrants its publication, we have nothing to do with it. Take, for instance, the New Orleans, St. Paul, Atlanta or Buffalo journals. They worthily represent the local profession of their cities; which ought to have journals to represent them. We have the desire to live on terms of amity with them; they would be of no use to us, and would be very unwise were they to join our combination. They fill their places better than we could, for they can give to local matters the space which we could not afford, and which would not be relished by the greater part of our readers. If they joined us, local pride would prompt the organization of new journals to take their places; and the result would be that the subscribers would desert us for the local journals. Hence, there is no conflict of interests between us and them. But there are other journals which are differently situated. Two or more occupy a field for which one is sufficient; and some of these could join us to their own great advantage and that of the others in the same field.

One of the oldest American Medical journals has just ceased publication, after a long and reputable career; after money had been spent and the labors of men of

[1] Texas Health Journal.

intellect lavished upon it. They built up a valuable journal whose revenue was yet insufficient to warrant its continued publication. So that the material results of these labors were wiped out, when its publication ceased. Instead of that, had the journal been merged in our weekly, its excellent editorial corps added to our own, THE TIMES AND REGISTER, would have been a better journal, its readers would have had more varied matter presented to them, the advertisers of both journals would have had the combined circulation of both, and the contributors would have had a larger circle of readers. The income, which was insufficient for the support of an independent publication, would have been a material aid in improving one already self-supporting. Everybody knows that the cost of running a few thousands of extra copies is not very large, after the first cost of setting up a journal, so that the expense to us of supplying the subscribers of another journal is not nearly so great as the cost of independent publication. Our readers will now see why the success of our plan is certain; as the four parties concerned in a medical journal, the subscriber, the publisher, the contributor, and the advertiser, each receive benefit.

The publishers of really valuable journals will be benefited by our operations, even more than we ourselves are, by the removal of competitors. If a city has two local journals and we take in one, all who desire a local journal will subscribe to the other; and it will be our interest to favor that one by liberal clubbing rates, etc., so as to induce them to take both the local journal and our own. With the cutting off of unnecessary journals, all remaining will be better off. This seems so evident, that it should be the aim of every one of our contemporaries to favor and to imitate our movement.

It is singular that there are scarcely any persons who will not be favored by our success. We may, perhaps, except the smaller sort of advertising agents, who favor the little journals, which are weak enough to be bullied into granting double and triple discounts; but as the interests of every one else are subserved by extinguishing such agents, this is a strong point in favor of our plan.

As this matter is of interest to medical journals everywhere, we invite the freest discussion and criticism. If there are flaws in our reasoning, if there are elements of uncertainty which we have not taken into account, we would like to know them.

ABSTRACT OF THE ARTICLES OF PARTNERSHIP

—OF—

THE MEDICAL PRESS COMPANY, LIMITED,

OF PHILADELPHIA,

Publishers of THE TIMES AND REGISTER.

BE IT KNOWN, that the subscribers desiring to form a partnership association for the purpose of carrying on a printing and publishing business in the city of Philadelphia, under and by virtue of the Act of the General Assembly of the Commonwealth of Pennsylvania, entitled "An Act authorizing the formation of partnership associations," in which the capital subscribed shall alone be responsible for the debts of the Association, except under certain circumstances, approved the second day of June, A.D. 1875, and the various supplements thereto, do hereby set forth and certify as follows, to wit:

The names of the subscribers are: William H. Pancoast, of Philadelphia; William F. Waugh, of Philadelphia; H. W. Hancock, of Philadelphia; Allen H. Still, of New York; John V. Shoemaker, of Philadelphia; Geo. Wharton McMullin, of Philadelphia.

The total amount of capital is $50.000, divided into shares of the par value of $50.00 per share.

The character of the business to be conducted is printing and publishing books and periodicals.

The name of the Association is The Medical Press Company, Limited.

The managers selected in conformity with the provisions of the aforesaid Act of Assembly are William H. Pancoast, H. W. Hancock, Allen H. Still, and William F. Waugh; and the officers are William H. Pancoast, Chairman; H. W. Hancock, Treasurer; Allen H. Still, Secretary.

Witness our hands and seals, this 7th day of May, A.D. 1889.

WILLIAM H. PANCOAST, [SEAL]
WILLIAM FRANCIS WAUGH, [SEAL]
HENRY W. HANCOCK, [SEAL]
ALLEN H. STILL, [SEAL]
JOHN V. SHOEMAKER. [SEAL]
GEO. WHARTON MCMULLIN. [SEAL]

State of Pennsylvania, County of Philadelphia, s.s.

On the 7th day of May, A.D. 1889, before me, the subscriber, a Notary Public for the Commonwealth of Pennsylvania, residing in the city of Philadelphia, personally appeared the above-named William H. Pancoast, Wm. F. Waugh, H. W. Hancock, Allen H. Still, John V. Shoemaker, and Geo. Wharton McMullin, and acknowledged the foregoing to be their and each of their acts and deeds, and desired the same recorded as such.

Witness my hand and official seal the day and year aforesaid. J. MONTGOMERY GREENE, [SEAL]
Notary Public.

Recorded May 8, 1889, at 10.

NOTE.—Since the foregoing was executed no transfers of stock or changes in the partnership have been made. THE MEDICAL PRESS CO., LIMITED.

PILOCARPIN IN TRAUMATIC TETANUS.—Dr. Cassati reports three cas s of traumatic tetanus cured by the injection of large doses of chlorhydrate of pilocarpin. He inoculated with tetanus nine rabbits, and all recovered except two. Recovery was rapid, but in every case there was a relapse after the first disappearance of all tetanic symptoms. This relapse always terminated in recovery or death. The symptoms disappeared a few hours after the injection, with the exception of trismus, which continued until recovery. Animals inoculated with tetanus bear doses of pilocarpin which would infallibly destroy healthy animals.—*Hospital Gazette.*

Annotations.

THE ELIXIR OF LIFE.

DR. ERNEST LAPLACE, who has been with Brown-Séquard within a not very remote period, strongly dissents with those who look upon the French physiologist as in his dotage, and affirms that he is still in the full possession of his mental faculties. His opinions are, therefore, to be received with the respect due to his great achievements, and his theory should have an impartial examination. We need not more than advert here to the improbability of any lasting effect being produced by these injections of testicular fluids. There is a disease which sweeps into the arms of death all who escape from other fatal ills, and that is old age. The periods of physiological activity and of subsequent decay come with the same unerring certainty as the succession of the seasons. Numerous experiments have been made, in fact, the world has been scoured, in the endeavor to find means of prolonging life, or, at least, the period of sexual activity. It cannot be said, however, that there has been any success in this search. Stimulants to the sexual appetite exist, but they are not lasting in their effects, and serve simply to more quickly exhaust the little vitality remaining. Since Hufeland's day no one has thought it well to prepare a work upon the art of prolonging life; and we may doubt, with Erasmus Wilson, if the art has made much progress since Hufeland wrote his book, now a century old. While all works upon medicine may be said to treat of this art, yet none have treated the subject in the simplest and most direct form, apart from the treatment of disease. In these latter days, when the profession is so overcrowded, it is likely that honor and profit would result if one were to take up as a specialty the art of prolonging the lives of aged persons and chronic incurables. But even if the effects reported by Brown-Séquard do not prove to be permanent, or really beneficial in the long run, it is probable that he has discovered a most valuable and powerful stimulant; one which may prove useful in other than the affections for which he used it. In the low stages of fevers, in anæmias, in many cases where a powerful stimulant to the exhausted vitality is needed, the testicular fluid may prove useful. There are such cases when alcohol does not answer; where strychnine is powerless, phosphorus and nitro-glycerin too evanescent, and ordinary tonics fail completely. In these, and in true neurasthenia, as well as in phthisis, the new remedy may find a place; provided the remarkable observations of Brown-Séquard are verified by other investigators.

Viardot has endeavored to eliminate from the experiments with the testicular fluids the effects of imagination. He described in glowing terms the results of the new method, and then injected pure water instead, but the patients found no relief. This is not satisfactory, however, as it is not always possible to carry conviction through simulated enthusiasm. Had he selected another physician, who believed in the method, and allowed him to address the patients, he himself believing that he was using the true fluid, the conditions of the experiment would have accorded with those found in actual practice.

ONE OF THE DANGERS OF TEA-DRINKING

Horace in one of his beautiful odes advises a friend to observe the "golden mean," the advice probably having as little effect as it has at the present day.

The difficulty of keeping this highly desirable mean is especially noticeable in the matter of stimulants. Just as the system is likely to become tolerant of any drug, by long taking, larger and larger doses being required to produce the same effect, so it is with stimulants. But with this latter class there is an additional danger that of passing from a weak to one of a stronger character.

Simple increase in amount ceases to give the necessary support, and the subject replaces his mild first with a more potent second.

The evils of tea-drinking *perse* are well-known, but we believe that the editor of the *Quarterly Review of Narcotic Inebriety* is the first one to call attention to the possible secondary consequences of this habit. He says that to the habitual tea-drinker who nerves herself for special efforts by taking large draughts of strong tea, there comes a time when this fails of its accustomed benefit.

If the habitué happens to be one surrounded by rather low moral impulses, she is likely to take to the alcohol habit; but if, on the other hand, she has a high social position to keep a reputation at stake, she will probably form the more secret but not the less dangerous habit of opium eating.

As long as a person takes stimulants simply for their taste he is comparatively safe; but as soon as he begins to drink for the effect, then he is running into danger. This subject at any rate merits more attention than it has yet received.

GOOD IN EVERYTHING.

JUPITER PLUVIUS is giving us what we consider rather more than our proper share of his attentions this summer, but these violent showers and huge floods are not an unmitigated evil. On the contrary, frequent flushings of a city's conduits and an occasional flushing of a nature's great waterways are of undoubted benefit. But just as a war may be of good to a nation, though of much ill to many individuals, so a flood falls hard on some, whilst laving a country's face.

A river's border is chiefly occupied by the lowest classes, those who are utterly careless about every hygienic precaution; so it comes to pass in time that the river's bank is lined with every species of abomination, both to the eye and to the nose, and becomes a capital pestilence incubator. The detergent waters, *en rampant*, change all this, and what they do not take along to the all-receiving sea, they at least cover with a non-conducting layer of mud. There is no cleanser so good as an abundance of water, but to do good it must run swiftly; and whilst running swiftly it is likely to take along more than we consider necessary. Nevertheless floods do good.

NOTES ON ACQUIRED LEPROSY.

DR. HUTCHINSON (*Brit. Med. Jour.*), in an interesting article upon this subject illustrated by the histories of some twelve cases, claims that the specific germs of leprosy are introduced into the system of previously healthy foreigners either by direct contagion or in the food, especially in the consuption of potted fish, which seems to be a favorite dish in the leprosy districts of India. From a study of the cases quoted, he arrives at the following conclusions :

1. That one not inheriting any taint may acquire leprosy by residing in a locality where it is endemic.

2. That such acquisition may be effected wholly without exposure to hardship or poverty.

3. That the malady may come to an end in the course of years during residence in a healthy district.

EXPRESSION IN THE TREATMENT OF TRACHOMA.

WE have received from Dr. A. E. Prince, of Jacksonville, Ill., an interesting paper, entitled, Expression in the Treatment of Trachoma, read by him at the meeting of the Illinois State Medical Society in May. He opens his remarks by calling attention to a singular "method employed in the treatment of chronic follicular trachoma which has found its way into few of the journals and none of the text-books." He says that the first reference to the subject is to be found in v. Graefe's "Archiv. für Ophthal.," 1883, by Mandelstamm, who, he says, speaks of the efficacy of squeezing, by means of the thumbs, in the treatment of trachoma. He goes on and describes how the thumbs are to be placed, etc., but nowhere do we find it in Mandelstamm's article.

It is true that the first suggestion or mention of this squeezing the follicles out that appeared in any article in Europe was in a paper, Der Tracho-matösa Process, von Dr. E. Mandelstamm, in v. Graefe's "Archiv.," Bund 29, Abtherling I, 1883, but we remember well the practice and teachings of Dr. P. D. Keyser, Wills' Eye Hospital, in this city, for years before that date, of the advantages of pressing out the follicles in certain forms of granular conjunctivitis; and in a paper, Some Ophthalmological Observations During Ten years' Service (1872–1882) in Wills' Eye Hospital, which he read before the Medical Society of Pennsylvania, in May, 1883. He recommends the pressing or squeezing out of the granulations as having been found very beneficial in thickened tissue and apparent loss of vitality. He describes the method as easily done by pushing the finger, nail outward, well under the turned-up lid, and then pressing with the finger of the other hand on the exposed conjunctiva. A little yellowish-white sago-like kernel springs out, leaving the whole tissue much softer. See Transactions of the Medical Society of Pennsylvania, Vol. XV., 1883. In looking over Mandelstamm's article, he nowhere describes a method for the treatment of granular conjunctivitis, only touches upon it lightly in his paragraph on treatment, page 100, by recommending the pressing ut or pricking of richly or well-developed follicles. Dr. Holz, of Chicago, in his article in "Knapp's Archives of Ophthalmolagy," June, 1886, was the one who deecribes the technique with the thumbs, etc. In looking over the success of this simple treatment of such a troublesome and tedious disease, it is really astonishing how little has been said about it in any articles or books treating this subject. Dr. Keyser's article being the first notice of the method in this country, Dr. Holz following in 1886, and now Dr. Prince giving his successful experience with the same, and it is one that, from the successes we have seen in the clinics of Prof. Keyser in the Wills' Eye Hospital and Medico-Chirurgical College, we feel sure that if adopted more universally it would be of great benefit to the many suffering patients who frequent the numerous clinics.

NATIONAL ASSOCIATION OF DENTAL FACULTIES.

THIS Association met at Saratoga Springs on August 6, 7, and 8. Out of twenty-eight dental colleges, eighteen were represented by delegates, representing institutions which were pledged to abide by the action of the Association.

The delegates adopted resolutions requiring the colleges to exact an examination preliminary to matriculation, and compelling the students to attend a three years' graded course. The resolutions passed by a two-thirds vote, which was subsequently made unanimous. They are to take effect from the beginning of the winter term in 1891–2. This date was adopted as a concession to the schools which are departments of medical colleges, whose course extends only over two years, and was designed to give these institutions time to lengthen their course of medical study. These were almost the only opponents of the resolutions.

It will thus be seen that the dental profession has taken a decided step in advance; one which places it ahead of the profession of medicine; and in fact puts the latter into the position of requiring less time for the study of the whole science and art of healing than modern dentists demand for the acquiring of a small portion of the same art. The action of the Association will be endorsed by all the dental colleges. In fact, they will be practically compelled to do so, as Dental Boards exist in many States, which are united in an Association of Dental Examiners. This body has the power of forcing any recalcitrant college into conformity with its reqnirements by refusing to recognize its diplomas without examination. A Baltimore college defied the Association for one year; but was glad to come into the fold before the opening of the next term.

The Association of Dental Faculties has been in existence for five years, and in that short period has accomplished three decided reforms in dental education. First, it put a stop to the practice of allowing practitioners of five years' standing to enter the graduating class. Then it established the graded course, with preliminary and junior examinations; and finally, it has instituted the great reform herein recorded. One result of this action will be to increase

by one-half the cost of the dentist's course of instruction; as the same body regulates the fees to be charged at dental colleges, and the student has now to pay for three terms.

It will thus be seen that the dental profession is much better organized than the medical; and that this is made possible largely through the influence of legislative enactments; further, that this has made possible an advance in dental education which could not have been secured otherwise; as the weaker schools would have held back those desirous of lengthening the course. The difficulties in the way of procuring suitable legislation are much less in dentistry, as there are no homœopathic or eclectic dentists.

SUPRAPUBIC CYSTOTOMY.

H. F. HERRING, M.R.C.S., M.B. (*Brit. Med. Jour.*) reports the results of thirty-one cases of suprapubic cystotomy, comprising all the operations of this nature performed by Sir Henry Thompson, and extending over the period from 1865 to the present date of this number. Two were performed by the old method as practised before the adoption of Garson's modification, both of which resulted fatally. The twenty-nine cases of the new operation include eleven for tumor of the bladder, only one of which was fatal, death resulting from pyæmia; and eighteen for calculus with three deaths, showing on the whole a considerable degree of success, especially when we note that "all of these cases represent the most advanced and the most complicated examples of disease."

In the performance of the operation the chief points to be noted are a full distension of the rectum associated with a moderate distension of the bladder, a small abdominal incision thus avoiding the use of a ligature, and an opening into the bladder sufficient to admit one finger only, by this means rendering stitching unnecessary.

DISEASES OF THE PROSTATE.

THE treatment of *chronic prostatitis* as recommended by Dr. Matthew Berkeley Hill (*Brit. Med. Jour.*) is general and local. The non-astringent iron preparations, nux vomica and strychnine as tonics, belladonna if there be micturition during sleep, and ergotine when there is much enlargement of the organ, with aching, constitute the general treatment. Locally, he employs the cold sitz bath of a temperature of from 50° to 35° F., taken once or twice daily, at first for one or two minutes, and gradually prolonging to ten minutes, the cold douche on the perineum, daily enemata of from two to four ounces of cold water, beginning at a temperature of 45° F., and gradually lowering to 35°, and in the later stages of the disease injections of ten minims of a solution of silver nitrate of a strength of 20 to 30 grains to the ounce, which must be repeated at intervals. In prostatitis arising from masturbation or excessive venery, one drachm of the fluid extract of salix nigra, three times a day, will often check the involuntary emissions, while too speedy ejaculation during copulation may be relieved by the use of the fluid extract of damiana.

In the later stages of the treatment of *tuberculous prostatitis* antisepsis is the main point to be observed. Dr. Hill recommends for this purpose the cleansing of the bladder by repeated small injections of boric acid solution, to be followed by an antiseptic solution consisting of two grains to the ounce of sulphate of quinine. A still more powerful antiseptic is an emulsion of iodoform, the formula of which is: iodoform, 2 parts; mucilage, 4 parts; glycerin, 2 parts; water, 20 parts. One or two drachms of this will remove all fœtid ammoniacal urine and cause a marked improvement in the condition of the patient. If there be much pain experienced while washing out the bladder, an injection of cocaine previously given will overcome this difficulty.

Letters to the Editor.

L'ELIXIR DE VIE.

IT is better to be out of the world than out of the fashion, and when the rage for pumping every invalid's bowels (who had a cough) full of sulphuretted hydrogen gas, or analagous ill-perfumes, was at its height, and all the great professors and their satellites were devoting their energies and their pens (those of them who could write) to letting us know how far up they could shove the wind—or how many cubic miles—no! feet, they could induce the sufferer to hold, I found from the remarks of friends anxious for my temporal (or temporary) welfare, that it was a mistake for me to ignore the prevailing fad, and to stick to old-fashioned remedies.

Now that Brown-Séquard has rejuvenated himself and set every one wild after his open secrets, I am going to redeem my former mistake. Thus far I have treated six patients with the "elixir of life." The medicament is easily procurable, and the patients too. Following out the advice of the great experimentalist, I injected into the chest muscle of an old gentleman, aged seventy-six, a drachm of liquid, and waited the results. In fifteen minutes his pulse has risen twelve heats, his face was flushed, and he declared that he felt thirty years younger already. In half an hour he was back to normal, all except the presumed rejuvenesence, but next day he came for more, the liveliness having vanished. He got another dose with similar results. I told him to wait a week before returning. He has, if his neighbors (who know of his enterprise are not jealous of him), been casting sheep's eye at the ladies on our block, but whether this is because Richard is a man again, or not, I don't know. He is a great gallant, anyhow. Two others underwent a similar experience, but their behavior, so far as I can learn, is all that can be required of them. They will return, probably, after awhile.

Now, the apparent effect of the hypodermatic injections in these three individuals was precisely what might have been expected from persons who, failing from age, were buoyed up by expectation incident to reading the fulsome reports so widely published in

the daily press under the guise of reports from men more or less eminent as quacks, holding high places in public esteem.

But the liquid used in the cases above noted was simply diluted gum arabic water!

The fourth patient was an old maid, and in her case the mixture was gluvine testicular "juice," as fashion has already christened it. A young but salacious tom-cat sacrificed his virility on the altar of science partly to please a friend who, in a Christian spirit, didn't want after awhile to trouble her neighbors with midnight warblings, and partly to afford me an opportunity to test the matter fairly. The usual crushing admixture with distilled water, and filtering were practised, the injection given, and the anticipated result followed. She was certain for two days that her vigor had returned—then it disappeared. Her associates considered that her volubility was more pronounced, but aside from that nothing startling was noted.

Two other injections in males used up my stock in trade. These gentlemen could not discover any change in sensation or ability to work harder than they ordinarily do. As my opportunities are better for experimenting on nervous patients than in the ordinary family practice, I intend to try further with such varied material as can be got, and after awhile I may have more to report. Meantime it strikes me that albuminous solutions injected into the general circulation are not particularly beneficial, or to be recommended too highly, if some of the reports on produced albumenuria are to be trusted. Care must also be used to avoid septic trouble, for butchers are not always truthful about the age of their produce.

246 North Twentieth Street.

RADICAL CURE OF FISTULA IN ANO AND HEMORRHOIDS BY ELECTRICITY.

I WOULD call the attention of the profession to more rapid methods of curing fistula in ano and hemorrhoids, coupled with safety and their radical extermination.

Having devoted years to this branch of the healing art, many times with tedious and unsatisfactory results employing the much talked of Brinkerhoff and other methods, I challenge the world to compare results with the methods I now use in the cure of fistula in ano, be there one or a dozen openings. I employ an electrolytic battery of about 12 ampére power with sufficient of the cautery element to subdue any hemorrhage that may perchance occur. My portable battery that I take to the patient's house is about six inches by ten long, and ten inches high, with two cells, and built chiefly for quantity, charging it with tri oxide of chromium and sulphuric acid; the method of procedure is this; the battery is first charged and the patient's bowels thoroughly emptied by means of an astringent injection, I then place the patient on his side and with the Shotwell rectoscope or other suitable specula, the inner opening is located, or if it be an external incomplete fistula, the side opening of the rectoscope is so turned that the possible opening is in view. The patient is, of course, under the influence of an anæsthetic. I then straighten out the fistulous track next nearest the anus, with a stiff steel probe of sufficient length having an eye near its introductory end, and if the sinus does not quite open into the bowel, perforate the intervening tissue till the eye of the probe is distinctly seen in the rectroscope, and leaving it there I next introduce a lance-pointed probe, having also an eye near its end about three-eighths of an inch farther from the anus into the solid structure and parallel with the fistulous track till its eye is also seen penetrating the bowel in the opening of the rectroscope; the eyes of both probes are then threaded with the opposite ends of a No. 24 platinum wire about ten inches in length, and both probes are then withdrawn, leaving the wire *in situ* forming a loop, both ends are now secured to an electrode, the electric current turned on, and the loop drawn through the partition, in its passage destroying the membrane which lines the fistulous track. No dressing is necessary, as it is well known that no wound heals more kindly than those made by a battery, the bowels, however, must be kept locked up for at least a week (longer is better), when the patient gets up a well man, complete union taking place by first intention. The above method I have employed in many instances with complete success. For hemorrhoids and prolapsus ani, I employ a similar treatment, no matter how large the protrusion or how long the patient has suffered; first bringing the growths all outside the anus, and in one treatment of a few moments the work is done and is always successful, followed by no hemorrhage or unpleasant symptoms or pain. And should your many readers desire further information, I shall be only too glad to give the same gratis to all who may apply, by addressing me at Grand Rapids, Mich.

W. S. Shotwell, M.D.

The Polyclinic.

JEFFERSON HOSPITAL.

HERE is a girl of twenty years of age, who has suffered for seven months from trouble in her right breast. It began to enlarge at that time, and has steadily continued to do so, giving her at the same time much pain.

A number of different diagnoses have been made, and she has finally been sent here in order to have the breast removed, under the belief that it is the seat of a scirrhus cancer. Though it is quite possible to have a cancer at her age, nevertheless I do not think this is one; if a tumor at all, it rather resembles a rapidly growing sarcoma.

But from the heat and sense of semi-fluctuation, I am inclined to suspect an abscess; though, strangely enough, this possibility has not been suggested by anybody else who has examined the case, probably because abscesses of the breast are so rare in a nullipara.

My first attempt with the exploring needle elicits no pus; but at the second, in a different place, you see pus escaping; and the diagnosis is now clear.

Making an incision at this point, I insert a grooved director, find the direction of the pus chamber, and make a counter-opening at the other end. My finger finds another passage radiating from the first incision, and I must accordingly make another opening. Besides these, we have discovered a pus chamber disconnected from the others and on a lower level; this is also freely opened; all my incisions, as you notice, radiating from the nipple. These cavities will now be syringed with the bichloride solution, drainage-tubes passed through each; and we shall expect, with this thorough drainage, that the patient will be up and about in a few days.—*Barton.*

Society Notes.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON ORTHOPÆDIC SURGERY.

Stated Meeting, March 15, 1889.

A. B. JUDSON, M.D., Chairman.

CICATRICAL CONTRACTION OF FINGERS.

DR. A. M. PHELPS presented a patient on whom he had operated four weeks ago for restoration of motion to the fingers, which had been flexed in the palm by a cicatrix in the wrist of eight years' standing.

He had freed each tendon from the cicatricial tissue and had secured healing by blood-clot, with the hope that new sheaths would be formed in the clot. The wound was dressed antiseptically, and the first dressing was changed at the end of three weeks. The prospect of recovery of motion was good.

DR. R. H. SAYRE said that Paget had long ago recognized the organization of blood-clot after subcutaneous tenotomy. The case presented by Dr. Phelps shows that advantage can be taken of it after open incision under antisepsis.

HYSTERICAL EQUINO-VARUS.

DR. N. M. SHAFFER presented a patient, a girl of twelve years, who had been affected for ten weeks with hysterical equino-varus and rhythmical movement of the left foot. The talipes was reducible manually, but the motions were persistent. There was inability to walk, the result of the disability of the quadriceps extensor group. Before coming under Dr. Shaffer's observation, plaster-of-Paris had been applied to the limb for several weeks, but without benefit.

DR. A. B. JUDSON thought that choreic elements were seen when the patient attempted to walk. He recalled a case of rhythmical myoclonus reported by Dr. Peckham in the "Archives of Medicine," in 1883, in which the patient had been subjected to a great variety of treatment, and recovered finally after the hypodermic use of atropine.

DR. S. KETCH suggested treatment by hypnotism.

DR. R. H. SAYRE thought that the case illustrated the fact that abnormal muscular contraction can produce degrees of deformity as marked as those caused by bony distortion.

DR. L. W. HUBBARD thought the case allied to chorea, being the result of nerve irritation or exhaustion. He suggested absolute rest or recumbency for a long period, with efforts to improve the nutrition.

DR. A. S. HUNTER had treated with success a case of hysterical hip by the administration of ignatia amara. The use of this drug in a number of cases of this kind has led him to value it highly when the disturbance was limited to groups of muscles only; but he thought it was of little value in the treatment of general choreic conditions.

DR. V. P. GIBNEY had had a favorable effect in a case of rotary spasm of the neck, from the fluid extract of gelsemium, given in five-minim doses, and pushed almost to toxic effects.

DR. H. W. BERG said that the contractions in the case shown could not be due to nerve lesion, because it yielded so readily to manual replacement. Where there is irritation of motor nerves, as in spastic paralysis, it is extremely difficult to reduce the limb to a proper position. He suggested the ordinary treatment of chorea with electricity to make an impression on the mind rather than on the nerves.

THE MANAGEMENT OF HIP-JOINT DISEASE.

The paper of the evening was read by DR. PHELPS, entitled, The Management of Hip-joint Disease from an Anatomical Basis.

In regard to the pathology of hip disease, Dr. Phelps believes that it is a local tubercular affection, due to accidental inoculation, and not to a constitutional or strumous condition. Following Volkmann, Albert, and Konig, he believes that the inflammation, at first simple, becomes tubercular by inoculation, and then purulent. The irritation of the peripheral extremities of the nerves in or about the joint produces muscular spasm, which, in turn, distorts the joint by trauma, aided by the bacilli of tuberculosis.

In regard to treatment, he relies on mechanical treatment, believing that if we immobilize a joint and remove the intra-articular pressure, nature will take care of the tuberculous material. His experiments on dogs has convinced him that immobilization of healthy joints does not produce anchylosis. Encouraging motion in an inflamed joint is a violation of the surgical law that an inflamed part requires rest.

He believes that the muscular spasm, which is a most serious element of destruction, should be overcome by extension, and that while extension is necessary to secure immobilization, it is not sufficient by itself. He therefore resorts to a combination of extension and fixation; the extension always to be in a line corresponding to the axis of the neck of the femur.

Treatment, as a rule, should be begun in bed, extension being made in two directions, *i.e.*, toward the foot-board and laterally, the body and well leg being fixed to a long splint extending to the axilla. If the deformity does not yield to extension properly applied, the tissues at fault should be divided subcutaneously, or by open incision. Abscesses are to be incised through their entire length, and thoroughly scooped out and washed, strict antiseptic precautions being observed.

Distention of the capsule should be relieved by aspiration or incision; then traction will not produce pain.

He exhibited a patient in a portable bed, which is an ingenious substitute for the wire cuirass, made with a board cut in an outline of the body, and plaster of Paris. The child is laid on the board, and then the whole enveloped with plaster-of-Paris bandages from the foot to the axilla. The plaster is then cut away in front, the interior comfortably padded, and the patient held in place by lacings or bandages. Extension and fixation in bed are to be continued until the active symptoms and the deformity have entirely disappeared, and the spasm of the muscles is no longer present. Adults are then given crutches, and a portable splint which has a perineal crutch, extension by adhesive plaster, an abduction bar, and an upper (thoracic) ring to prevent flexion and extension at the hip. Children, after treatment in bed, are to have the portable bed, and then the portable splint, with or without the high shoe and crutches.

Dr. J. Ridlon was much pleased to hear the author of the paper take the ground that hip cases should be cured without deformity. He recalled a case of a patient in which the muscular spasm had been relieved by pinching the muscle. The child was very thin, and it was found that when the adductors were separated from the other muscles, and the belly of the muscle was pinched without any attempt at fixation, there was as much relief as could have been afforded by lateral traction.

Dr. Shaffer said that the paper had suggested to him the importance of separating in our minds the disease from the deformity. It is a question how far we are justified in meddling with the deformity, which is simply an expression, or, so to speak, a symptom of the disease. In his experience, attempts at speedy reduction of the deformity had been followed by disastrous results. Nature gives a very positive indication in the acquired position of the thigh—that in which the immobilization of nature reaches its maximum, and the diseased parts receive the greatest relief from reflex muscular spasm. If we forcibly interfere with this effort on the part of nature, we inflict a distinct traumatism.

On the threshold of treatment, the important question is, not whether traction is to be made in the line of the shaft of the neck, but how to secure an artificial immobilization in the position nature assumes as the one that affords the most protection to the inflamed parts. He believed that if the joint were protected from traumatism; in other words, if traumatic contact of the inflamed joint surfaces is removed, and this can readily be done by the use of portative apparatus without entailing immobilization of the entire body from the head down, the joint is placed in the best known local condition.

The portative traction treatment is compatible with fresh air, sunlight, and moderate exercise, which are the best means of combating the tubercular disease, and the tubercular diathesis. More lives have been saved, and better results have been thus secured, than by any other method which has been thoroughly tested.

Dr. R. H. Sayre agreed with Dr. Shaffer as to the importance of maintaining the general health, and the inadvisability of general immobilization of the body, if the diseased joint could be controlled without it. He thought that complete immobilization of the hip-joint in young children was very difficult to secure; and that the movement that stopped short of producing muscular spasm and pain was not harmful. For poor children particularly, he thought the portable bed was an admirable contrivance.

The relief obtained in some cases by pinching the muscle could be explained on the supposition that it stopped the reflex action of the muscle. It is known that firm constriction of the belly of a muscle will, in certain cases, abolish spasm.

Dr. Chas. L. Scudder, of Boston, advocated a more frequent resort to the results of experiment on the cadaver. He recalled Dr. Bradford's experiments made in 1880, in which it was found that in an adult a force of one hundred pounds was not sufficient to separate the head of the femur from the socket; while in the shallow and not yet completely ossified acetabulum of a young child, a moderate force caused separation, and still less force was required in the fœtus. Dr. Scudder believed that in hip disease of children a tractive force of from three to five pounds would separate the joint surfaces as was illustrated at the Children's Hospital, in Boston, in the case of a young boy who had hip disease and night cries. The joint cavity was opened and a small quantity of pus evacuated. While the boy was under ether, it was found that traction made with the hand separated the joint surfaces to such an extent that the finger could be placed between the head and the acetabulum.

Dr. Hubbard thought that no one at the present time held the opinion that anchylosis is caused by immobilizing the joint affected with chronic inflammation. He had found it difficult to get anchylosis in cases where it was desirable, as in disease of the knee. The first object is to give rest to the joint, which is best done by traction; not to separate the surfaces, but to overcome articular pressure which leads to muscular spasm. He believed the long hip splint gave sufficient immobilization for all practical purposes. It is more easily managed than the portable bed of Dr. Phelps, which from neglect would be likely to cause excoriations. As the disease seems to be a struggle between the tubercle bacilli and the vitality of the organism, he thought it especially important to place the system in the best possible condition to resist attack. He had rarely seen constitutional disturbance from abscesses which had been let alone, although in exceptional cases acute and painful conditions are certainly greatly relieved by surgical interference.

Dr. Judson commended the title of the paper. It was an admission that hip disease is not to be cured by treatment, but so managed that the almost inevitable recovery by natural processes should be with the minimum of disability and deformity. He thought that more emphasis should be placed on the importance of protecting the joint from the traumatisms of standing and walking, as is done by the use of Hut-

chison's extra long crutches and high sole on the well foot. But in every case there are long periods of exemption from pain, when this simple apparatus will be discarded. The ischiatic or perineal crutch of the hip splint, however, cannot be wilfully discarded; and when it is seen that the rack and pinion not only furnish traction, but also a convenient means of adjusting the length of the upright, the hip splint appears to come very near perfection as an instrument for the management of hip disease. He had never recognized either the trauma, said to be caused by reflex muscular contraction or the alleged mechanical counteraction of the muscles by traction. He believed, and had always held, that the hip splint mitigates reflex muscular contraction by allaying the inflammation which gives rise to it. This it does by arrest of motion and prevention of pressure; motion being arrested by traction brought about by the use of the key, and pressure being averted by the perineal or ischiatic crutch, which makes the limb a pendent member. As the inflammation is resolved the reflex muscular contraction ceases.

The last annual report of one of our orthopædic institutions contains a table, from which it appears that there have been under treatment 371 cases of disease in the hip; 6 in the shoulder; 85 in the knee; 3 in the elbow; 27 in the ankle; and 5 in the wrist; an aggregate of 483 in the lower, and 14 in the upper extremity. Shall we draw the inference that the incipient osteitic focus is found only or chiefly in the cancellous tissue of the lower extremity, or that a focus in the upper extremity more readily undergoes resolution by reason of its comparative exemption from violence? If the latter view is correct, it follows that the limb is to be made a pendent member by the persistent use of the axillary or ischiatic crutch at the earliest recognition of the disease. In some cases an early diagnosis may be facilitated by the following simple method:

Let the patient sit on a table with the legs hanging and the knees separated; in this position, swinging the leg laterally is possible only with rotation of the femur; and if one leg oscillates in a less arc than the other, it induces or confirms a suspicion of the integrity of the joint.

He did not believe in treating abscesses and sinuses excepting indirectly through the general and local management of the bone disease in which they have their origin.

Dr. Gibney was in favor of securing absolute immobilization, but sometimes he would rather have less perfect immobilization, if by so doing he could secure a change of air and climate, with the consequent improvement in the general nutrition.

Ordinary hip disease is managed satisfactorily by the portable traction splint, with or without the rack and pinion; and he had been agreeably surprised with the facility with which these patients ran around in the tenement houses. They come to his clinic only every three or four weeks for adjustment of the apparatus; and during these intervals engage in the most active sports; they certainly do not lie in bed in dark rooms and die of pyæmia. It is unsafe to put these children in an appliance like a cuirass or the portable bed, unless one is certain of being able to see and attend to them at short intervals. It had been his lot to see cases in which he had been unable at times to obtain proper coöperation on the part of the patient's family. He had often seen abscesses burrowing up to the spinal column and down to the knee; and such cases seemed to baffle even attempts at surgical interference. We must be guided a good deal by circumstances, and if we can protect the hips from trauma and give the patient the benefit of outdoor exercise, abscesses will generally be insignificant.

He believed in correcting the deformity speedily, if necessary, by dividing tendons and bone under an anæsthetic, for by so doing we save much time and lose nothing.

In regard to aspirating the joint over distended with fluid, it was almost impossible to diagnosticate an over-distended hip-joint. The position of the limb does not depend on the quantity of fluid in the joint, but is due to reflex spasm, and the efforts made by the child and nature to secure fixation.

Dr. J. H. Gardner described an experiment on the cadaver in which great force was applied without separating the surfaces of the hip-joint. He also cited a case in which it had been necessary to keep the hand applied to the face for nine weeks in the course of a plastic operation on the nose. At the end of this time there was no limitation in the motions of the elbow and wrist.

Dr. Ketch believed that hip disease is so often characterized by exacerbations that all attempts at a division into stages are of no practical value. He thought that the hip splint could be often of use for the reduction of deformities even in those periods when the patient is confined to his bed. In general, he believed it was a great mistake to make use of any apparatus which can be entirely left to the care of the patient or family for long periods.

The explanation of the relief of pain by compression of muscles was to be found in an involuntary action on the part of the patient which secures fixation and traction at the same time.

Dr. Berg, speaking from the standpoint of the general practitioner, who frequently saw children in the very beginning of hip disease, related the histories of three cases which had presented the symptoms of early hip-joint disease, and yet recovered perfectly after rest in bed for a few weeks. He now insisted on all such patients remaining in bed for several weeks before commencing any other treatment.

Dr. Phelps, in closing the discussion, said that many cases in tenement houses, whether treated by the long traction splint or by the portable bed, are deplorably neglected; but this does not argue against the use of either apparatus; it simply illustrated one of the difficulties with which all practitioners have to contend. He valued the portable bed because he desired immobilization of the affected joint, and this could not be obtained with splints having joints in them, and not including the trunk. He could relieve his patients better in bed during the period of deformity, and so adopted this method of treatment.

He had seen patients in England who had been in bed for several years, and were still in excellent health. He did not, however, advocate prolonged bed treatment. Believing that the cases in question are inoculations of the bacillus tuberculosis on a previously inflamed surface, and not instances of constitutional tuberculosis, he explained the frequency of tubercular joint diseases in the lower extremity, by the statement that the joints of the lower extremities being more subjected to traumatic inflammation, furnish good ground in which the bacillus of tuberculosis could more readily reproduce itself.

He had presented his honest convictions, and hoped to report his cases later in such a way that others could disprove his statements, or he could substantiate his views.

Book Reviews.

THE CLASSIFICATION, CORRECT DIETARY, AND TREATMENT OF DISEASES OF THE SKIN, AS PRACTICED IN THE BELFAST HOSPITAL FOR THE SKIN. By HENRY S. PURDON, M.D., L.R.C.P. Belfast: William Mullan & Son, 1889.

This is a small volume of thirty-six pages, intended to be used as a sort of noter or ready reference-book.

The author has classed the diseases as much as possible according to their causation, instead of adhering to the ordinary methods. The matter is well arranged.

He does not favor ointments, but pomades. These are put up in sticks covered with tinfoil, and can thus be carried about by the patient and rubbed on at any time. We think this plan much neater than that of giving an ointment.

BOURNMOUTH AS A HEALTH RESORT. By A. KINSEY-MORGAN, M.R.C.S. Illustrated. London: Simpkin, Marshall & Co., 1889.

Nearly every health resort of any name has now its special book, and the author feeling that Bournmouth's just claims have not been heretofore properly recognized hastens to fill the want. Since he is the medical officer of health, he is in a position to write understandingly. The usual information is given with regard to history, geology, water supply, climate, and balneology. As a work of the printer's art the book is only mediocre, and the illustrations miserable.

A TEXT-BOOK OF HUMAN PHYSIOLOGY. By AUSTIN FLINT, M.D., LL.D., etc. etc. New York: D. Appleton & Co., 1888.

This now famous text-book comes to us very much improved, and in fact so rewritten as to embrace the latest discoveries and teachings of the science without increasing the size of the volume. The author, whose experience and learning fully entitle him to the high position he occupies, has made a work that is a model in that it is severely confined to didactic teaching. It is notable for the absence of foot notes or references, and the comparatively few allusions to the costly and cumbersome apparatus of the accepted physiologcal laboratories; the evident design being to secure at all hazards concentration to the purpose of the book. This view of the plan will explain the absence of foot notes which, however troublesome they may be to arrange accurately, no doubt are rarely used by the ordinary student; although to one who proposes to investigate accurately the opinions of other writers, or advance views of his own, they are of great value as a convenient means of promptly consulting that which already has been recorded. The loss of time to the reader by such reference notes interrupting him, and their increase of the bulk of the book, are not sufficient to remove a regret that data so desirable should have been left to be sought elsewhere or in other works on physiology.

There can be little doubt of the wisdom of omitting the long and necessarily verbose descriptions of apparatus, much of which is so costly and so little used, as to make the explanation of the cuts of the appliances appear at best as lumbering the book and swelling it with matters suited for a manufacturer's catalogue. If such descriptions are excusable to show how delicate and difficult the work has been, they at best are tedious to follow and serve more to advertise the owner and manufacturer of the apparatus than really to add anything new. This is additionally true since Landois & Sterling's book has the descriptions and they are in that work so arranged by different fonts of type that they may be passed without trouble at the pleasure of the reader. Indeed such experimentation, with rare exceptions, but repeats the facts that for years have been confirmed.

The novelties of discoveries, so numerous of late, are treated with becoming attention, showing the advanced and liberal position of the author. His right to sit in judgment upon their values in the explanation of physiological functions may be seen in every part throughout the work. It is seldom that one can justly estimate the importance of his own efforts and observations, and many hold that a teacher is the better if he have no pet theory or themes of his own to champion. Even if fairly impartial he may, by dwelling comparatively too long upon matter of minor importance, cause distorted mental views of facts, detracting from the harmony by reason of undue magnification of secondary points.

It would take up a space unwarranted in this review, to recount all the later changes in and additions to the science of physiology, since the third edition of this book was published. Suffice it to say that one cannot profess to keep abreast of the current of the day in a study like this where so great is the activity and so far reaching and ingenious is the research, and be without an epitome of the latest information, of which this book is an admirable exponent.

Little, if any doubt is left upon the mind of the reader as to the views of the author, when contested points are under discussion, except in cases that are yet vague by reason of the differing opinions among the most advanced thinkers and investigators.

The adoption of the new chemical nomenclature and the metric system of expression of quantities, are evidence of the reformation of the times and the retention of the English weights and measures, plainly indicate how the change will probably arrive at completion, after a general education that

will familiarize students with both the old and the new methods.

An example of the brevity with which the author treats of some views, that in the past have been discussed at much length, is found on page 10 where the structure of the blood corpuscles is described in about ten lines and a half. In these he clearly expresses the opinion that they are homogeneous and without investing membrane and that "the appearances . . . . which have been supposed to indicate the presence of shreds of ruptured ossicles, are not sufficiently distinct to demonstrate the existence of a membrane." Perhaps the substitution of the words "often found" for "distinct" would be an improvement. One cannot forget the unique specimen of Prof. J. G. Richardson, wherein a crystal, apparently of hæmoglobin, seemed to distend like a tent, what might have been a membrane of a blood globule, whose contents were evacuated. Certainly there was in this specimen no lack of distinctness or definition, and the membrane like matter, had to all appearances, been originally globular and was complete and without a missing portion.

Upon the same page the theory of the formation of the red blood globule from the leucocyte, receives a dangerous thrust in the sentence. "The red corpuscles appear before the leucocytes are formed; and it is mainly the fact that the two varieties consist in the bloodvessels which has given rise to such a theory."

On page 14 he calls attention to the fact that the leucocytes appear "in fœtal life, before the lymphatics can be demonstrated. They appear in lymphatics before these vessels pass through the lymphatic glands, in the fœtus anterior to the development of the spleen, and also on the surface of mucous membranes, so that they cannot be considered as produced exclusively by the lymphatic glands, as has been supposed." Further on, however, he says: "The blood, also, in passing through the spleen has been shown to gain largely in these corpuscles," and he then proceeds to remind the reader of the bearing of these facts upon leucocythœmia, and also that "pseudo-leucocythœmia, presenting the anatomical characters and general symptoms of leucocythœmia, without an increase in the leucocytes of the blood, has been accurately described."

The subject of the blood-plates or plaques microcytes, or invisible or elementary corpuscles described by Manschultze, Hayem, Bizzozers, Neumann, Laker, Osler, and others, although on inviting one to the investigator, is most sternly dealt with by our author, after a brief description of them and how they are demonstrated he says: "Physiologists have no knowledge of the uses of the blood-plaques. The relations which have been supposed to exist between these bodies and the development of the other corpuscular elements of the blood, the phenomena of coagulation, etc., are as yet indefinite and uncertain."

If more evidence were needed to show the prevalence of the idea that it is a text-book and in such brevity has rare merit; we will refer to p. 104 where is the consideration of "Passage of the Blood-Corpuscles through the Walls of the vessels (Diapedesis)." In this paragraph of about twenty lines is described the migration of the leucocytes "through the walls of the bloodvessels, either by means of small orifices (stomata), or by a kind of filtration through the substance which unites the borders of the endothelial cells." Without lengthening the subject by reference to the discussion of the pros and cons, Waller and Cohnheim are referred to as the authors who first invited to the study and that, according to Hering, "the red corpuscles pass through the walls of the vessels only when the pressure is sufficient to produce transudation of the blood-plasma." Here, however, he might have added from Landois that "Hering observed that in large vessels with perivascular lymph spaces, the corpuscles passed into these latter, hence, cells are found in lymph before it has passed through lymphatic glands." Furthermore, that "quinine not only arrests the movements of the leucocytes when applied to them directly, but when injected into the circulation of a frog to the amount of $\frac{1}{20000}$ part of the animals weight, the leucocytes no longer pass through the walls of the capillaries (Binz)." T. C. S.

The Medical Digest.

Intestinal Occlusion Treated by Electricty.—M. Hérard commences by injecting into the rectum a certain quantity of salt water, after which he passes a current of galvanic electricity. Of nineteen observations there were ten cures.

For M. Hérard this treatment is exempt of all inconveniences and dangers; it should always be employed when the other customary methods have failed.

—*La France Médicale.*

Action of Medicaments on the Utero-ovarian System During Menstruation.—To verify the popular opinion that certain medicaments modify the menstrual flow, M. Lambi Atthil took occasion to administer medicinal doses of ergot, strychnine, and quinine during this period. In each instance the menstruation remained normal.

—*Gazette de Gynécologie.*

Treatnent of Puerpural Septicæmia by Curetting the Uterus.—Chartier claims that this treatment is indicated in all cases where intra-uterine injections are insufficient to rapidly reduce the temperature, especially if there remains any placental dèbris. Even peritonitis is not a contraindication.

—*Bulletin de Thérapeutique.*

Operation for Incontinence of Urine.—M. Gersung, of Vienna, presents a new operation for this troublesome complaint. It consists of torsion of the urethra (the operation was performed on a child of eleven years), following its axis, and then in the fixation of its external extremity in its new position. This operation is only indicated, however, when the sphincter of the bladder is defective.

—*La Tribune Médicale.*

VACCINATION OF THE NEWBORN.—In a communication to the Society of Medicine, at Berlin, M. Wolff demonstrates that the public and the physicians are wrong in rejecting early vaccinations in infants.

It has been pretended that the newborn are refractory to the vaccine virus; the experiments of the author have demonstrated that this opinion is absolutely erroneous. In all his cases the general condition has remained unchanged; the fever is generally absent, while in older children it is most generally severe.

Again—and this is the point which has been contested—the newborn acquire by vaccination new protection, as has been proved by attempts at revaccination.

In conclusion, we can vaccinate a few days after birth, not only without inconvenience, but with decided advantage.

This fact is important, because smallpox is very dangerous the first year and particularly so the first month after birth.

Since the year 1876, 5578 persons have died of this disease; of this number there were 2122 children one year of age, that is to say probably not vaccinated. In effect, in Prussia the laws recommend that children shall not be vaccinated before the end of the third month, and allows exemption from vaccination until the age of ten years.

In England, on the contrary, all children must be vaccinated before the age of three months; this example should be imitated.—*Revue Médicale.*

ANTISEPTIC VINEGAR.—In his recent volume on "Hygiene," Dr. Duiardin-Beaumetz gives the following formula for the *vinaigre pennès*, which he considers one of the most useful of disinfectants, more especially because of its general applicability.

℞.—Salycilic acid 30
Acetate of aluminum 30
Alcohol of eucalyptus globulus . 100
Alcohol of verbena 100
Alcohol of lavender 100
Alcohol of benjamin 100
Acetic acid 100

—*Journal d' Hygiene.*

PURGATIVE CHOCOLATE (Giraud fils).—

℞.—Cacao in powder (oil extracted) . 50 grammes.
Pulverized sugar . . . . . 100 "
Castor oil . . . . . 50 "
Vanilla powdered . . . . . q. s.

Sig.—Make into large pastilles; 3 to 6 will be sufficient to purge a child.

DRY CORYZA.—

℞.—Powdered starch,
Boric acid,
Tincture of benzoin (Siam) in equal parts.

Mix and dry by gentle heat.

Union Médicale du Canada.

OPHTHALMIC MIGRAINE (Piéchaud).—

℞.—Syrup of ether . . . . . 60 grammes.
Antipyrin . . . . . 3 "
Citrate of caffein . . . . . 0 gr. 20
Cocaine hydrochlorate . . . . . 0 gr. 20.

M.—Sig. A tablespoonful every three hours until relieved.

—*Revue de Thérapeutique.*

NASAL CATARRH (Garageorgiadès).—

℞.—Pulverized iodoform,
Powdered acacia . . . . . ăă 2 grammes.
Hydrochlorate of cocaine . . . . 0 gr. 15.

M.—Sig. Use as snuff.

TREATMENT FOR EXCESSIVE MENSTRUATION (Rheinstadter).—

℞.—Ergotine dialysed . . . . . 10 grammes.
Distilled water . . . . . 70 "
Glycerin . . . . . 20 "
Salycilic acid . . . . . 0 gr. 2.

M.—Sig. One teaspoonful diluted with three tablespoonfuls of water, to be injected into the rectum once a day after a stool.

INFANTILE DIARRHŒA (Critzman).—

℞.—Salycilate of bismuth . . . 1 to 2 grammes.
Laudanum of Sydenham . . 1 to 5 drops.
Infusion of tea . . . . . 60 grammes.
Syrup of raspberries . . . 20 "
Rhum . . . . . 15 to 20 grammes.

M.—Sig. One teaspoonful every two hours.

Or,

℞.—Lactic acid . . . . . 2 grammes.
Distilled water,
Syrup of raspberries . . . . ăă 50 grammes.

M.—Sig. One teaspoonful every half hour.

—*La Tribune Médicale.*

PILLS FOR THREATENED MISCARRIAGE (Lafferta and Cuzzani).—

℞.—Pulverized gum resin of assafœtida . . . . . 60 grammes.
Simple syrup . . . . . 6 "

For sixty pills: Commence with two pills a day and then increase one pill every two or three days. The results are excellent.

PREVENTION OF DENTAL CARIES.—

℞.—Rose water . . . . . 500 grammes.
Tannin . . . . . 8 "
Tincture of iodine,
Tincture of myrrh . . . . . ăă 5 "
Iodide of potassium . . . . . 1 "

M.—Sig. One teaspoonful in a glass of warm water, t. i. d.

Revue de Thérapeutique.

LAXATIVE POWDER.—

℞.—Powdered anethum,
Powdered senna,
Sublimed sulphur . . . . . ăă 6 grammes.
Powdered cream of tartar . . 2 "
Powdered licorice . . . . . 8 "
Powdered sugar . . . . . 25 "

M.—Sig. Teaspoonful to a dessertspoonful to be taken at night in a little water.

LAXATIVE PILLS.—

℞.—Sulphate of iron,
Extract of aloes,
Extract of hyoscyamus . . ăă 1 gramme.
Alcoholic extract of nux vomica . . . . . 0.15 centigrammes.

Make fifteen silver-coated pills.

M.—Sig. One at night,

La Normandie Médicale.

Medical News and Miscellany.

EPIDEMIC dysentery prevails at Warsaw, Ia.

BRISTOL is suffering from an epidemic of babies.

A DEATH from actino-mycosis is reported in New York.

MERCY HOSPITAL, in Pittsburgh, is crowded with typhoid fever cases.

THE Hay Fever Convention will meet next month at Bethelem, N. H.

SMALLPOX rages in lower Egypt, whence we get large quantities of rags.

AN Egyptian mummy shows evidences that when its owner resided therein he had the gout.

A HOME OF REST for nurses is proposed in London. There is a great army of nurses in London.

THE number of deaths from cholera infantum in Philadelphia is steadily decreasing from week to week.

A WILLIAMSPORT barber reverses the Brown-Séquard method, and makes young doctors look ten years older.

SHIRLEY DARE says that if women would resort to the fruit-cure every season they would not be troubled with liver spots.

SUNSTROKES are common in Southern Russia, where the thermometer during two weeks registered 144°, or over, every day at noon.

ATLANTIC CITY has escaped the wet weather prevalent along the Atlantic coast. The water has been rather too cold for bathing until the present week.

MISS A. L. LOCK, Superintendent of the University Hospital, has been exonerated of the charges that her management was inefficient and careless.

THE continued rains in and about Philadelphia have developed an unusual amount of malarial disease; even in localities where it has not been known for many years.

DR. D. A. HARRISON, Medical Superintendent of the Kings County Insane Asylum, at St. Johnsland, L. I., has been elected Superintendent of the Delaware Insane Asylum, at Farnhurst, at a salary of $2300 per annum.

DR. GRANT BEY, Fellow of the Society of Science, Letters and Arts of London, has been appointed an honorary member of the Council and Examiner, to hold office from November 10, 1889, until November 9, 1892.—*Egyptian Gazette.*

DR. HAMMOND proved conclusively, not long ago that men ought never to die, and that if they could only attain the ideal conditions of life, they would live forever. This was not a particularly practical idea, but it was rather more scientific than the plan of rejuvenating men by hypodermic injections. Still, the world is never too old for new experiments.

—*Times.*

DR. W. S. ROLAND'S appointment as Pension Examiner at York, Pa., has been withdrawn, as he was not a soldier, and Dr. B. F. Spangler appointed in his stead.

THE New York Board of Health has printed 10,000 copies of nine rules for the guidance of those who attend consumptives. Great stress is laid upon the danger of patients sleeping in the same room with a consumptive person, and consumptive mothers are warned against nursing their children.

SATURDAY, August 10, was donation day for the Children's Seashore House, at Atlantic City, N. J. We understand that a large sum of money is needed for the summer's work of this most commendable institution. Money can be sent to Dr. W. H. Bennett, or to E. A. Sibley, No. 136 North Fourth Street, Philadelphia.

AUGUST changes in the staff of the Presbyterian Hospital. Dr. De Forest Willard retires as Visiting Surgeon and Dr. W. G. Porter takes his place; Dr. R. G. Curtin succeeds Dr. O. P. Rex as Visiting Phpsician. The resident staff will consist of Dr. John Traill Green, Dr. Seymour Van de Meter, Dr. B. W. McGalliard.

THE latest development of the automatic machine is a Dr. Cureall, in Holland. It is a wooden figure of a man, with compartments all over it, labeled with the names of various ailments. If you have a pain find its corresponding location on the figure, drop a coin into the slot, and the proper pill or powder will come out.—*Record.*

DR. BENJAMIN LEE, Secretary of the Pennsylvania State Board of Health, has written President Harrison, suggesting that some portion of the national epidemic fund, which now amounts to over $100,000, should be expended in dredging and diking the Conemaugh River at Johnstown.

The President has referred the letter to Surgeon-General Hamilton.

WILLIAM WOOD & CO.'s *American Druggist* says "our antiquated and always boastful contemporary" accuses some of its "Infant Contemporaries" of having stolen a part of its telegraphic report of the A. P. A. Convention at San Francisco. The *American Druggist* says it "could find nothing worth stealing in the skeleton," and makes it the occasion of a protest as follows:

"This is a small matter, but we make it the occasion of uttering just here a protest against this illiberal, boastful, and contemptible habit, indulged in by whatever journal or newspaper, of trying to make capital for itself by throwing mud at rival or competing publications. We do not feel envious at the prosperity or good fortune of any of our competitors; we would rather be on friendly terms with them than not, and it is not the policy of the publishers or their representatives, *either within the printed pages of the journal or outside in speeches at convivial gatherings, to violate all journalistic proprieties by vicious attacks on people who may be engaged in the laudable enterprise of minding their own business.*"

LAST year there were 2800 deaths in Philadelphia from consumption, 1708 from inflammation of the lungs, 891 from cholera infantum, 795 from old age, and 621 from typhoid fever. Thus, it will be seen that a Quaker is more apt to die of old age than of typhoid. And yet we're not happy!

A RIVAL for the new rejuvenator has already appeared. In a Wisconsin town there is an alleged discovery of pearls in clams, and the town has dropped all other avocations to engage in clam shucking. Among others, a woman, who had been confined to her house for twenty years with rheumatism, recovered at once, and sallied out to search for the treasures.

JUDGING by the expressions of opinion in the secular press, we are in a hopeless minority in regard to the Schuylkill water. Would it not be well for the County Medical Society to appoint a committee to investigate the subject and report upon it? Any conclusion reached by this body would have weight with the public; who are left too much to the daily press for information on matters of public hygiene.

TENTH INTERNATIONAL MEDICAL CONGRESS.—WE, the undersigned, do hereby give notice, that according to the resolution passed at the Washington meeting, September 9, 1887, the Tenth International Medical Congress will be held in Berlin.

The Congress will be opened on the 4th and closed on the 9th day of August, 1890.

Detailed information as to the order of proceedings will be issued after the meeting of the delegates of the German Medical Faculties and Medical Societies at Heidelberg on the 17th of September in the current year.

Meanwhile, we should feel sincerely obliged if you would kindly make this communication known among your medical circles, and add in the same time our cordial invitation to the Congress.

VON BERGMAN, VIRCHOW, WALDEYER.

DR. J. EDWARD TURNER died at his home in Wittau, Conn., July 26, aged sixty-seven years. He was born in Bath, Maine, and attended lectures in Philadelphia, and was licensed to practice by the Maine Medical Society. Early in his career he became impressed with the fact of the disease of inebriety and the need of asylum treatment for such cases. He abandoned his profession and gave his entire time and energy to establish an asylum for this purpose. Twenty years after, he projected and built the first asylum in the world at Binghamton, New York, for inebriates. This was changed to an insane asylum by the "Tweed Ring," but lived long enough to show the value and need of such places. Over seventy different asylums for inebriates in the world now in operation, date to Binghamton and Dr. Turner as the great pioneer and projector of this new field of reform. The later years of Dr. Turner's life were spent in efforts to have the Binghamton Asylum restored to its original purpose. He was one of the best known men among reformers in this country, and in many respects was a remarkable man, who not only impressed his day and generation, but left a permanent work of reform for the future.

THE *Ledger* closes an editorial upon the water supply and its relation to typhoid fever, with the following sensible expressions:

"Now we insist on having it understood that what is above set forth is not for the purpose of disputing anybody's theory or effecting any contemplated movement for the purchase or sale of the city's water supply—a thing not likely to occur—but is wholly and solely for the purpose of adding to the public's information on an important subject, and for the purpose of fortifying our own belief that the increase and decrease of typhoid in Philadelphia are largely due to other influences than the Kensington water or any other in our water system; and finally, for the purposes of reasserting the fact that, notwithstanding all said on the subject, Philadelphia's official returns of sickness and death prove it to be one of the two or three healthiest cities in the world."

IMPROVED METHOD OF AMPUTATION OF THE PENIS.—The most unpleasant symptom following amputation of the penis is the funnel-like retraction of the urethra, which causes the patient endless discomfort. Dr. Assaky overcomes this by dissecting the pars spongiosa of the urethra from the penis, for about an inch beyond the superficial incision. Then the corpora cavernosa of the penis are cut through from below, leaving about an inch of the urethra protruding beyond. The tunica albuginea and the skin are then brought over the stump of the pars cavernosa and stitched around the protruding urethra. This will retract to some extent, leaving a very natural looking meatus.—*Hospital Gazette.*

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from Auugust 6, 1889, to August 12, 1889.

WOODHULL, ALFRED A., Major and Surgeon. Is granted leave of absence for two months on account of sickness, by direction of the Acting Secretary of War, with permission to leave the Division of the Missouri. Par. 5, S. O. 178, A. G. O., August 3, 1889.

JANEWAY, JOHN H., Major and Surgeon. Leave of absence for two months is hereby granted, with permission to apply for an extension of two months. Par. 3, S. O. 52, Headquarters Division of the Pacific, July 29, 1889.

COCHRAN, JOHN J., Captain and Assistant-Surgeon (now on duty at Fort Adams, R. I.). Will report in person, by direction of the Secretary of War, to the commanding general, Department of the Platte, for temporary duty with troops, en route to and at the summer camp at Fort Robinson, Neb. Upon the completion of this duty will return to his proper station. Par. 10, S. O. 180, A. G. O., August 6, 1889.

GORGAS, WM. C., Captain and Assistant-Surgeon. The leave of absence granted, by direction of the Secretary of War, in S. O. 84, July 3, 1889, Department of the Missouri, is extended two months. Par. 2, S. O. 182, A. G. O., Washington, August 8, 1889.

BANISTER, WILLIAM B., First Lieutenant and Assistant-Surgeon. Is relieved from further duty at Fort Wingate, N. M., by direction of the Acting Secretary of War, and will report in person to the commanding officer, Fort Grant, Ariz., for duty at that station, relieving Captain Arthur H. Taylor, Assistant-Surgeon, who, upon being relieved, will proceed to Fort Wingate, N. M., and report in person to the commanding officer thereof for duty at that post. Par. 4, S. O. 178, A. G. O., August 3, 1889.

Medical Index.

We purpose in this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Address delivered at the forty-third annual meeting of the medical superintendents of American institutions for the insane. American Journal of Insanity, July, 1889.

CLINICAL OBSERVATIONS

ON SOME OF THE EFFECTS OF DIRECT AND INDIRECT TRAUMATISMS OF THE BRAIN.

(A paper read before the Second Annual Meeting of the National Association of Railroad Surgeons, held at St. Louis, Mo., May 2 and 3, 1889.)

BY R. HARVEY REED, M.D.,

MANSFIELD, OHIO.

Surgeon B. and O. R. R., Member American Medical Association, American Public Health Association, British Medical Association, etc.

CASE I.—William McB., aged twenty-three, a farmer. Was always an unusually strong, healthy lad, and with the exception of an occasional attack of indigestion, was never ill.

In the fall of 1879 he fell backward off a shed, falling some ten feet, and striking the ground with his head, causing a slight depression of the skull over the right coronal suture, commencing close to the sagittal suture and extending outward about an inch. He received no surgical attention, and soon recovered, being able to be out the following day, and apparently suffering no special inconvenience from the fall.

In the fall of 1882, while helping to haul some logs, he was kicked by a horse, whose feet struck him on the shoulder and side of the neck, which threw him under a heavy log-wagon, loaded with five logs averaging a foot in diameter and fifteen feet in length. A front and hind wheel of the wagon ran over him just across the hips as he lay with his face on the ground. From this accident he received little or no injury outside of a few bruises, from which he soon recovered, excepting a little soreness along the track of the wheels.

In February, 1886, he contracted mumps, which metastasised to the testicles, from the effects of which he suffered considerably.

In the spring of 1887, he contracted rubeola, and became quite sick with more than the usual amount of lung symptoms, and complained of a great deal of soreness across his chest, and he never felt as strong physically afterwards.

In August, 1887, he came home from school feeling ill, and continued to decline in health for about a month, when he became so debilitated as to get what his parents called "fainting spells," after which he recovered sufficiently to ride to the city, a distance of five miles, where he consulted Dr. J. W. Craig, who discovered a swollen condition of the left testicle, which he strapped and gave the young man a tonic. The testicle, however, subsequently suppurated and had to be lanced twice.

About the first of November, 1887, he returned to school, feeling much improved in his general health, which continued until about February 1, 1888, when it began to fail him, and a general muscular weakness was complained of. This increased until he found it necessary to call in a physician, where he was attending school, who put him on a general treatment for nervous prostration.

Notwithstanding this, he gradually grew weaker and weaker, until he was obliged to leave school and return home February 17, 1888. The writer was

called to see him Feb. 25, 1888, and found him suffering from great muscular weakness, which seemed to be general.

His temperature was normal, pulse 80, but rather weak; slight soreness complained of over abdomen and chest; other than that no pain was complained of. Respiration was normal, and the respiratory murmur could be distinctly heard over both lungs, which were normally resonant on percussion. There was no tympanitis, and the urine was normal, with the exception of the presence of large quantities of earthy phosphate and indican, as the following analysis shows: Sp. gravity, 1022; acid reaction; no albumen; no sugar; large quantities of earthy phosphates; indican in considerable quantities.

Microscopical.—Nothing of importance except large quantities of amorphous urates.

Bowels alternated from slight diarrhœa to constipation; pupils were normal; light did not affect the eyes; no headache, but mind slightly wandering, and there was a distinct impediment in his speech.

I saw him again on February 27. The difficulty in articulation had increased until there was almost complete aphasia, with great languor and drowsiness.

His appetite was poor, he would drink some milk and take a little broth when urged by his nurse. He complained of some pain over lower portion of right lung, and some tenderness over the bowels, which were kept open with an occasional dose of *hydg. cum creta*. From this time on the aphasia and muttering delirium increased. The latter, however, frequently alternated with an exceedingly noisy and occasionally boisterous condition, which had to be controlled with opium in full doses.

The tongue was dry and furred brown; pulse slow and irregular; temperature only slightly above normal, and some abnormal dilatation of the right pupil.

On February 29, Dr. J. W. Craig saw him in counsel with the writer, at which time his condition had become worse, and prospects of recovery very doubtful. The treatment during this time consisted in alteratives, with opium, salicin, and pure pepsin, with liquid nourishment in the form of milk and beef essence, the latter made fresh each day with an extractor. His condition gradually grew worse until he passed into a comatose state just before his death, which took place on March 3, 1888.

The post-mortem was held thirty-four hours after death in the presence of Dr. J. W. Craig, Dr. J. Harvey Craig and Dr. Frank McBride.

Rigor mortis was very marked. A slight depression was found in the skull, commencing near the sagittal suture on the right side, and extending about an inch along the line of the coronal suture. Removed calvarium and found some thickening of the skull and periosteum immediately under the external depression; found the dura mater congested, and tubercular degeneration of the pia-mater extending along the posterior portion of the right hemisphere from a point just anterior to the fissure of Rolando, and extending posteriorly to near the cerebellum, in close proximity to the median fissure; this tuberculous patch was from one-half to an inch in width, and about five inches in length. A patch of the same was found on the left side, commencing at about the same place, and extending posteriorally about two inches, and from a fourth to an inch in width.

The optic commissure was surrounded with organized lymph, having the appearance of white grape jelly, with a fine net-work of bloodvessels running through it, of which there was more on the right side than on the left. Just posterior to the lower portion of the fourth ventricle, and almost immediately opposite to the calimus scriptorius in the anterior portion of the arbor vitæ of the left cerebellum was found a blood clot about the size of a coffee bean, which was apparently of recent origin, yet of sufficient age to show signs of incipient softening, while the brain substance around it was beginning to undergo destructive degeneration.

The ventricles of the brain were filled with effusion, especially the lateral ventricles. The pons was very much hardened, almost as if it had been in alcohol. Extending in all directions from the blood clot, the brain was softened; the white substance having a yellowish appearance, which gradually faded out into the normal white, near the periphera of the white substance in both lobes of the cerebellum.

The pituitary body, corpora albicantia, tuber cinereum, optic thalamus, corpus striatum, corpora quadrigemina, and pineal gland, were all softened and degenerated, which softening extended out along the fissure of Sylvius, and involved the Island of Riel, especially on the left side.

On examining the thorax we found the pericardium firmly adherent to the sternum and the surrounding lung tissue, while both the lungs were completely adherent to the costal pleura and the diaphragm by the tubercular adhesion, although the lung substance itself was not tuberculous, but, on the contrary, with the exception of a little recent congestion, apparently normal..

The heart was normal in size and general appearance. On examining the abdominal viscera we found the omentum was as thin as a piece of brown paper, and was not only adherent to the parietes, but also to the visceral peritoneum.

The large and small intestines, spleen, pancreas, liver, bladder, and even the diaphragm, were all completely and firmly adherent to each other by old tubercular adhesions, that were almost impossible to separate.

The kidneys were slightly congested, but otherwise normal, as was also the bladder, which contained a quantity of urine. On opening the stomach and bowels they presented the normal appearance. The left testicle had undergone degeneration, and was atrophied to at least one-third its normal size.

CASE II.—On February 29, 1888, I was called to see Mr. J. McK., aged seventy, a farmer, who gave me the following history:

January 1, 1887, he was as well as he ever was, so far as he knew. On January 31, of the same year, he was taken with pain on the right side over the region of the liver, which lasted three or four weeks. After a few weeks remission, he was taken ill again (about the last week of April) with a severe pain in his head with "dizzy spells;" when this pain across the front

of the head was very severe he was troubled with nausea. Said he had been treated for pleurisy, "liver trouble," dyspepsia, and brain disease, and finally got a little better, but never fully recovered.

In August, of the same year, he commenced to get very short of breath, which difficulty had troubled him all summer, more or less. Never had any severe pain, except in his head. Never spit any blood. During this illness he called another physician, who pronounced his one lung "gone," and the other "going on the fly," and treated him accordingly. During the following November he had an abscess of the right testicle, since which time he said he had been failing more rapidly.

A third physician was called about this time, who pronounced his case one of malaria, and stuffed the old gentleman with anti-periodics for weeks without favorable results, after which he was "sidetracked" for an old quack, who lives up in the country a few miles. After diligently applying his "roots and herbs" for a season, he was dealt with after the manner of those who had preceded him, and, lastly, the author was called only a few days prior to his death.

When I found him, he complained of no pain in any place except in his head; his tongue was dry and red as a piece of beef. His appetite was poor, and he was not thirsty, only drank to wet his lips and tongue, and ate because he thought he ought; bowels never loose, but slightly constipated; stools light colored; urine scanty and rather high colored. Examined urine chemically, which revealed the following: Sp. gr., 1024; reaction acid; no sugar; no albumen; large quantities of earthy phosphates; indican in large quantities.

Microscopical Examination.—Nothing of importance except amorphous urates.

The patient was very much emaciated, and greatly prostrated, but his mind was clear and there was no trace of paralysis.

After examining the abdominal and thoracic viscera carefully, and finding everything substantially normal, with the above history, I was led to believe he had some organic brain disease, the exact nature of which I was uncertain of, but considered a grave prognosis in order, and so expressed myself to the friends.

With little else of interest other than above stated, he gradually grew weaker, and died March 7, 1888. The post-mortem was held fourteen hours after death. On examing the brain there was found to be general effusion throughout the sub-arachnoid spaces. A tumor was found attached to the choroid plexus on each side, and located just between the posterior portion of the thalamus opticus and the corpus fimbriatum.

The one on the left side was about the size of an ordinary hazel-nut, while the one on the right side approached the size of a small hickory-nut. These tumors were grayish in color, quite hard, and of a calcareous nature, undoubtedly having undergone calcareous degeneration subsequent to their acute stage, the lime salts having since filled the interstices of their fibrous capsules.

I sent the one tumor to Prof. Senn, of Milwaukee, for examination, who says: "I have examined the specimen sent me, and dissolved out about 33 per cent of the weight of tissue—phosphate of lime and carbonate of lime.

"Microscopically, stroma of connective tissue in various degrees of degeneration can be seen. I am inclined to believe, from the structure and the well-formed capsule, that it is an apoplectic cyst." The corpus collosum, corpus striatum, corpus fimbriatum, thalamus opticus, tænia semi-circularis, hippocampus major and minor, together with the fornix, corpora quadrigemina, and pineal gland, were all very much hardened, which condition gradually disappeared and became lost in the more normal condition of the brain near its periphery.

The medulla oblongata and pons varolii, and even the chord, shared in the hardening process already referred to. On examining the visceral organs, the lungs, heart, stomach, liver, kidneys, and bowels, were found in a normal condition, with the exception of a slight congestion of the liver, and the recent deposit of numerous tubercles over the hepatic capsule and along the intestinal tract.

Case III. — Miss C., aged twenty-five, Green Valley, Ohio. The first time I examined her was during the summer of 1887, when she was under the care of Dr. W. W. Pennel, of Fredericktown, Ohio, who, being absent at the time of my visit, subsequently furnished me the following history:

She was taken very suddenly ill on July 6, 1886, with complete aphasia while at work in a very hot room. When seen a few hours after she had considerable fever; pulse 120; unable to articulate, but perfectly conscious; no difficulty in protruding the tongue; left pupil dilated. The patient was of a rheumatic diathesis, having suffered from rheumatic endocarditis of the left side of the heart, resulting in numerous vegetable growths, one of which, in the doctor's opinion, had been dislodged and found its way into the middle cerebral artery.

On July 7, 1887, her condition was much the same, with the addition of paralysis of the right arm and leg, but did not involve the face; had a disposition to act hysterically. Temperature 103° F., pulse 120, and respiration 24. From July 8 to 15, her condition gradually improved. She commenced to articulate a word or so, and with that the paralysis of the right arm and leg gradually improved. Her mind was perfectly clear, and on being interrogated, complained of tinnitus aurium. An ophthalmoscopic examination revealed a congested condition of the vessels of the retina. Her improvement was quite rapid, and on August 4, she visited the doctor at his office, at which time she could walk very well, and had tolerably good use of her right hand. She could articulate very distinctly, though she often made use of the wrong word.

All through her sickness she was annoyed with occasional attacks of articular rheumatism. In December, 1886, she was seized with chills, which recurred daily, followed by a fever which ranged from 103° to 104° F., with a pulse varying from 120 to 130.

At this time a noticeable increase of the paralysis

was observed, which only lasted a few days and then gradually declined, and never was a marked symptom after that. On percussion over the left temporal region she complained of pain, and often sharp pain, which was confined to the left side of the head. The tinnitus continued, with dilatation of the left pupil. The appetite was poor, emaciation marked, night sweats very debilitating, and not controlled even with atropine. The menses ceased, and constipation set in. At no time was there nausea or vomiting. There was often insomnia, but at all times perfect mental equilibrium. The chills, fever, sweats, tinnitus, scintillations in the left eye, with dilatation of pupil, remained to a greater or less extent until May, 1887, when she gradually rallied. The chills ceased, and also the perspiring. She gained flesh, and her menses were again established and became fairly regular but scanty.

The tinnitus, partial aphasia and incomplete paralysis of right side, dilatation of left pupil, and occasional pain in the left temple continued.

In August, 1887, the chills, fever, and sweats returned, and continued for several weeks. This was followed with another decline of the symptoms, but the patient afterwards made a gradual rally, and seemed to gain in every way except as above stated. Suddenly, however, on the morning of November 22, 1887, after having been unusually comfortable the day previous, a cerebral bloodvessel ruptured whilst she was asleep in bed, causing death in a few hours.

The author assisted Dr. Pennel in conducting a post-mortem a few hours after death, which revealed an abscess of the brain located in the anterior third of the left hemisphere. The abscess was about the size of a large turkey egg, and wholly imbedded in the white substance of the brain, and was believed to be the result of an embolus, which degeneratad into an abscess, destroying the coats of one of the branches of the left anterior cerebral artery, producing its rupture, and resulting in death.

One of the peculiarities of this case was the perfectly normal appearance of the entire brain, excepting just the part involved by the abscess, which was encased by firm walls of brain substance, completely circumscribing its boundaries. By request, the examination was not continued further, and the exact condition of the rest of the body will ever remain a mystery.

CASE IV. — William S., of Mansfield, O., aged thirty-one; day laborer. During the summer of 1885, I saw him for the first time in counsel with Dr. Craig, with reference to an operation for his relief, at which time we obtained a part of the following history of his case, which I completed a few days prior to his death:

In March, 1880, he was accidentally struck on the back of the head with a ballast pick, while engaged at work as a section hand on the Erie Railway, causing a depressed fracture of the skull a little to the right of the crown. The injury knocked him senseless for a few minutes, after which he got up and walked home, a distance of some two miles. A homœopath was called in, who volunteered to let nature and the injury fight it out between them.

The stroke of the pick cut the skin, which soon became swollen as large as a hen's egg. The injury only disabled him for two weeks, when he returned to work, and for the next five years he labored as hard as he ever did. During this time "conservative" surgeons would point to him with pride and call attention to the achievements of their skill.

During all this time, however, he complained of his neck and back part of his head hurting him more or less.

In February, 1885, he became partially insane, which condition lasted for about five weeks, when that condition improved and his mind got apparently well, which was followed with what the doctors called "rheumatic pains," which were confined to his feet and arms, but gave place about the following July to paralysis of the left arm and leg, which increased until both motor and sensory nerves were almost completely paralyzed. This condition lasted nearly four months, when he commenced to improve, and kept on convalescing until he gained fairly good health, and resumed work again. He was unable to do heavy labor, so went to peddling, which he continued until about the middle of April, 1888.

About this time he seemed to give out all over. He had no special pain, but seemed to be completely exhausted. His weakness was increased by the suppurating of some of the cervical glands on the left side of his neck. This was followed with shooting pains through his abdomen. On May 17, 1888, I was called to see him for the first time since 1885, when I completed the above, and learned that wise (?) counsel had advised him against permitting either Dr. Craig or myself making any operation for his relief—a measure we had advised at our first visit in 1885, but which, on the advice of a lot of "old granny" doctors had been refused.

I now found that my patient was beyond all hope of recovery, and gave it as my opinion that the injury to the skull had resulted in the destruction of a sufficient portion of the brain substance to cause such a degree of inanition as to result in tubercular degeneration and death.

At this time there was no paralysis, slight aphasia, no headache of any consequence, marked suppression of urine, diarrhœa, with symptoms of subacute suppurative peritonitis. Baring a stupid, listless condition, his mind was apparently clear; pulse 130, feeble and irregular; a low grade of fever; skin moist; tongue coated very heavy; pupils dilated; feet swollen, with some ascites. The abdomen was tender and painful to the touch.

Urinalysis, made May 18, 1888: Sp. gravity, 1018; no sugar; no albumen; large quantities of urates, and bile-coloring matter; indican present in large quantities.

Patient died May 22, 1888. Post-mortem held twenty-six hours after death. Rigor mortis very slight. Suppuration of the cervical glands on the left side of the neck; emaciation quite marked; abdomen very much distended.

On removing the scalp we found the evidences of the two wounds. One evidently produced by some flat instrument was located over the sagittal suture,

and two inches above the posterior fontanelle. The other one showed evidences of having been made with a blunt instrument, and was located about an inch to the right of the sagittal suture, and on the same level with the former.

The first wound showed no evidence of any depression of the bone, while at the seat of the latter there was a depression about an inch long and a quarter of an inch wide. After removing the calvarium a bony tumor was found immediately beneath the depression above referred to, about the size of a hickory-nut in circumference, but only about half as thick. There was general thickening of the calvarium in the vicinity. All openings through the skull for the bloodvessels on the right side were obliterated, as well as the pacchionian depressions.

The meningeal grooves on the left side were larger than their fellows on the right. There was effusion within the dura mater especially on the right side, with the membrane somewhat thickened. There were numerous lymph adhesions, even dipping into many of the convolutions of the brain. Immediately beneath the depression in the cranium was found a small abscess located in the brain substance near the middle of the superior parietal gyrus, about the size of a hazel-nut, which was evidently a partially broken down tubercle, the pus of which had burrowed its way through the brain substance into the posterior portion of the right lateral ventricle, forming a small sinus between the abscess and the ventricle.

The bulbs of the olfactory nerves were softened and degenerated. There was general congestion and hardening of all the brain tissue with sclerosis of the spinal cord. Also marked effusion into both lateral ventricles, with degeneration and softening of all the brain tissue lining the lateral ventricles, especially toward the posterior portion, the anterior portion being lined with tubercular membrane. On examining the abdominal viscera, the intestines were found adherent to each other throughout, due to the tubercular inflammation, occasioned by the breaking down of thousands of tubercles which were scattered all over the intestinal peritoneum, from one end to the other.

Subacute-purulent peritonitis had thickened and destroyed the parietal peritoneum, whilst the peritoneal sac contained over two gallons of "creamed coffee" colored purulent liquid.

The stomach was adherent to the intestines and covered with tubercles, whilst that portion of the hepatic capsule that rested on the stomach was studded with tubercles also. The liver proper was normal, with the exception of being slightly congested and adherent to the diaphragm.

The lungs were normal, but were pressed upward until their lower margins were opposite the upper margin of the fifth rib.

The heart and pericardium were normal, as were also the kidneys, spleen, and pancreas.

CASE V.—Mrs. Sarah D., of Belleville, Ohio, aged sixty-nine years. Was severely injured on the night of March 15, 1888, by some murderer, who attempted to brain her with the pole of an ordinary hatchet. The old lady was feeble-minded prior to the injury, and was looked on by the neighbors as having been "queer" in her habits for years.

Her injury consisted in three wounds in close proximity to each other, on the left side of her head, evidently produced by three strokes from the pole of the hatchet, producing a compound comminuted fracture of the skull, the fragments of which were driven down upon the dura mater with great violence without lacerating that membrane however. The dura was forced down from one-fourth to one-half an inch on the brain substance.

Dr. E. Stofer, of Belleville, was called and removed the fragments of bone, which left an opening in the skull four and one-fourth inches in length, and from three-fourths to one and one-half inches in width, extending from a point one-half an inch inward from the external angle of the left eye, and from about an inch above the same posteriorly across the frontal bone, and penetrating into the anterior superior portion of the left parietal bone about an inch. The wound was widest at its middle and narrowed at either end.

After making a free incision lengthwise of the wound, and removing all the fragments of bone and raising them to place, the doctor cleansed the wound thoroughly. Uniting the edges of the scalp with interrupted sutures, he put on a light antiseptic dressing. The subject of this brutal assault was evidently injured during the forepart of the night, and lay in a cold house until eight o'clock the following morning before she was found and relief afforded.

When discovered she was wholly unconscious with stertorous breathing. Her pulse was slow and sluggish, but soon rallied after the operation, from fifty to ninety, and the respirations became natural. Consciousness returned in part, but did not improve much afterwards; has not improved much since. The aphasia was almost complete, the word "yes" being the only word she was able to articulate, and when asked any question, no matter what it was, her only answer was "yes."

She had complete paralysis of the right arm, and partial paralysis of the right leg. The left arm and leg were apparently normal. The pupils were always normal. Her appetite was good, bowels regular, and urine natural, but she had no appreciation of the calls of nature any more than a child. Notwithstanding the unfavorable circumstances following the accident, the wounds healed without any trouble, and when seen by the writer, May 24, 1888, were almost entirely closed, with no indications of cerebral hernia.

I was told by Dr. Stofer, through whose kindness I am enabled to give you the history of this interesting and instructive case, that at no time was there any marked constitutional disturbances, and but little suppuration.

Some months after I was informed by the doctor that Mrs. D. had died from an acute attack of dysentery, which proved fatal on the third day, but that her mental condition had never changed materially from that already reported. Unfortunately there was no autopsy made.

CASE VI.—On May 31, 1888, I saw Mr. E. L. S.,

of Perrysville, O., in counsel with the attending physician, Dr. J. F. Johnston, of that village, through whose courtesy I received the following history of this very interesting case: Mr. S., aged thirty, a telegraph operator, was injured early on the morning of March 8, 1888, while jumping from an engine, slipping and falling backward, striking the side of his head against a bolt on the tender, producing a compound comminuted fracture of the skull on the left side, immediately over the parietal protuberance. Drs. Scott and Son, of Loudenville, being the nearest surgeons of the Pennsylvania Company, were sent for to look after the wounded man, and were assisted by Dr. L. Firestone, of Wooster, another company surgeon, who, with Dr. Covert, of Perrysville, took charge of the case. After a number of pieces of the fractured and depressed skull were removed or raised to place, an opening, about the size of a silver dollar, remained in the skull, from which a small quantity of brain substance was removed, after which the wound in the scalp was closed with two sutures, leaving the dura mater unclosed and without a drainage-tube.

The wound was then dressed with a wash of laudanum and carbolized water, and the patient put under the influence of anodynes, with which he was kept stupefied for several weeks. The wound was dressed with this wash twice a day, and the discharges, which were quite profuse, removed.

About the last of March, or three weeks after the injury, a fungus cerebri commenced to make its appearance, which soon reached the size of a large goose egg. Various devices were adopted to get control of this extruder by the attending physicians who again called to their aid Dr. Firestone, of Wooster. All the devices proved fruitless, especially strapping down with sheet lead, which invoked a tendency to convulsion, which were promptly relieved by removing the pressure. At this time there was complete aphasia and paralysis of both the upper and lower limbs on the right side, and also the face on the same side.

The nurse informed me that it was seventeen days after the injury before an operation was secured from the bowels, and that the urine had to be relieved with a catheter, and the bowels kept open by the use of both medication and enemata. The prognosis of the attending physicians was grave. This was concurred in by Dr. Firestone, and no hope of his recovery was entertained.

About the 20th of April, the family decided to call Dr. J. W. Craig, of Mansfield, in counsel with the attending physicians, who, after examining the case, advised a strict antiseptic dressing to be applied, which, with good regimen, careful attention to the excretions, perfect quiet, and elevation of the head, he thought would at least give the man a *chance* to recover.

A few days later, Dr. J. F. Johnston, at the solicitation of the family, was put in charge of the case, with Dr. Craig for counsel, who placed him on the above outlined treatment.

During all this time consciousness never has been interfered with, not even when he was injured, being able to get up, and with some slight assistance, walk into the depot. After being carried home, he walked into his room and assisted in undressing himself. He has remained perfectly clear in his mind ever since.

About three weeks after the injury paralysis set in on the entire right side, involving the face, tongue, arm, and leg, which gradually increased until the paralysis became complete. This condition lasted about eight weeks, when sensation and motion both commenced to return, and they have been gradually improving ever since.

Aphasia commenced about the time the fungus cerebri began showing itself, which soon became complete, and lasted until about the latter part of April, when his powers of articulation gradually commenced to return, and have also steadily improved. I found the patient sitting up when I visited him and feeling comfortable, but still had some paralysis of the right side. He could walk around the room and use his hand a little. The aphasia was disappearing, and the patient able to talk pretty well, although unable to articulate some words. The bowels were regular, and he sleeps and eats well.

I found an opening on the left side of the head just over the parietal protuberance fully as large as a half dollar, from which there was still protruding a small fungus cerebri about the size of an ordinary walnut. This I learned was decreasing rapidly in size, and healing from all sides. No suppuration of any consequence at present. There was no headache, and the pupils were natural. There was no tinnitus aurium, no fever, and pulse was normal. The patient has consulted me a number of times since at my office.

The last time, about six weeks ago, when I observed that the fugus cerebri had long since disappeared and the scalp wound was entirely healed, whilst the paralysis had improved very much and was steadily becoming less apparent.

The patient was unable to either give or receive telegraphic messages, owing to the sluggish action of the brain, but his general physical condition was gaining daily.

Remarks.—It will be observed that we have reported two cases of direct traumatism with death, two cases of indirect traumatism with death, and two cases of direct traumatism with recovery and partial restoration of the functions of the injured brain.

Cases I and IV give histories of direct traumatism, the one received nine years, and the other eight years prior to death. There was temporary recovery in each case, followed by tubercular degeneration and death. In both the recovery from the primary injury was rapid and without a bad symptom.

In Case I the extra tension placed on the brain by continued study no doubt acted as an exciting cause in developing the sequellæ of the traumatism received years before, the symptoms of which were manifested by the so-called "fainting spells," which for a time subsided with rest, only to return, accompanied with a general breaking down of the whole system on his resuming hard study with all its increased mental tension and close confinement.

In Case IV we had a man who apparently recovered from a traumatism which left a mechanical pressure

on a portion of the brain. For several years he seemed to resist all this irritation with little inconvenience outside of continual pain in his neck and back of his head. He finally broke down under this abnormal strain with an attack of insanity, followed by neuralgia, and, finally, partial paralysis of the whole left side and general tubercular degeneration.

In Case I there were symptoms of the pneumogastric centers giving out first, and thus lowering the vitality and predisposing to tubercular degeneration. In this case, outside of partial aphasia coming on after his last illness had progressed for some time, he had no symptoms of either paralysis or mental disturbance until just a few hours prior to death, when some paralytic symptoms manifested themselves, associated with mental disorders.

In Case IV the failure of the nervous centers was announced by the sudden disturbance of mental equilibrium, followed by neuralgia and paralysis, with a general lowering of the vitality, resulting in tubercular degeneration. There was no marked paralysis in the latter stages of this case, excepting the slightest aphasia, notwithstanding the immense amount of brain destruction.

In both of these cases you will observe there were large qnantities of earthy phosphates and indican found in the renal excretions, the latter pointing, everything else duly considered, to destructive "disease of the spinal cord and its membranes, and especially derangements of the entire central and peripheral nervous systems."—*Tyson.*

In both there was marked tubercular degeneration of the brain as well as its membranes, together with tubercular degeneration extending to the abdominal and even the thoracic viscera.

From these two cases we draw the legitimate inference that traumatic injuries affecting the cerebrum may, for the time being, apparently recover, yet will undoubtedly act as a predisposing cause of a devitalized condition of the whole economy, and, finally, result in general tubercular degeneration.

In Cases II and III we have what may be fairly called indirect traumatism; that is to say, in the one case there was an apopletic cyst formed on each side of the cerebrum involving the choroid plexus, which afterwards underwent calcareous degeneration, thus not only producing a mechanical obstruction, but also inducing mechanical irritation of the brain substance itself.

The other case was due to the traumatic effect of an embolus producing a mechanical obstruction of one of the branches of the anterior cerebral artery, resulting in localized suppurative degeneration of the anterior portion of the left hemisphere.

In Case II we have neither paralysis nor a disturbance of the cerebral equilibrium, notwithstanding the general effusion throughout the subarachnoid spaces and ventricles, and sclerosis of the brain, together with the spinal cord.

In Case III, only one portion of the brain was affected, and yet we had aphasia and partial paralysis of the entire right side, with apparent gradual recovery, notwithstanding the presence of a large abscess, which finally destroyed one of the branches of the anterior cerebral artery, causing almost instant death.

In Case II, we had large quantities of earthy phosphates and indican excreted by the kidneys, which showed almost the same results from analysis as Cases I and IV. Unfortunately, in Case III, there was no analysis of the urine made. Like Cases I and IV, Case II was just beginning to develop general tubercular degeneration when death ensued. This condition we were not able to search for in Case III, owing to a request by the family not to examine the corpse further than the brain. Cases V and VI are both cases of a direct traumatism inflicted on the right side of the head, resulting in aphasia and paralysis of the right side.

In neither one was there any apparent derangement of the mental function, although, in Case V, there was complete loss of consciousness until the brain pressure was relieved, while in Case VI, there was no loss of consciousness, notwithstanding a portion of the brain substance was removed.

In Case V, there was complete paralysis of the right arm and partial paralysis of the right leg from the time of the injury, with little, if any, improvement at the time of my visit, nearly two months after the damage, and yet the dura mater was not broken and there was no escape of brain substance, while in Case VI, there was laceration of the dura mater and escape of some of the brain substance, and yet there was no loss of consciousness, and not even aphasia or paralysis until two or three weeks after the injury.

In fact, there was no evidence of loss of the cerebral function until after the fungus cerebri began to appear, the aphasia and paralysis increasing with the growth of the tumor, and also gradually disappearing with the fungus.

Conclusions.—1. That very slight injuries to the cranium may produce such an amount of cerebral irritation as to cause a fatal termination years after the traumatism is received.

2. That the brain, under certain circumstances, is capable of making a rapid recovery from a severe injury of the calvarium, producing a continuous mechanical pressure on some portion of the encephalon, from which it will promptly rally, and, for the time being, assume its normal functions and maintain them for years before it succumbs to the effects of the traumatism.

3. That we may have grave destruction of portions of the motor and sensory nerves without either anæsthesia, hyperæsthesia, or motor paralysis.

4. That an injury and escape of portions of the brain substance is not necessarily *immediately* followed with motor or sensory paralysis, or even loss of consciousness, although it may follow weeks subsequently.

5. That abscess of the brain, or traumatic cerebritis, accompanied with fungus cerebri, may each be followed with aphasia and motor and sensory paralysis.

6. That an apoplectic cyst may undergo calcareous degeneration, and thereby develop a mechanical irritation which will sooner or later prove fatal.

7. That an embolus may cut off the blood supply

of a certain arterial territory, and so devitalize that portion of the brain as to result in an abscess and death.

8. That grave injuries to the brain are liable to be followed with such a degree of devitalization of the economy as to favor general tubercular degeneration.

9. That the presence of indican in the urine is synchronous with cerebral degeneration.

10. That whilst there may be nerve cells capable of taking on definite functions, under certain circumstances, distributed here and there throughout different portions of the encephalon, yet clinical experience points to the bilateral centralization of certain nerve cells at certain definite points, the injury of which produces fairly definite and reliable results.

REPORT OF THE SPECIAL COMMITTEE ON DISEASES OF THE ALIMENTARY CANAL.

(Read before the Illinois State Medical Society at Jacksonville, May 21, 1889.)

By A. J. BAXTER, M.D.,
ASTORIA.

FUNCTIONAL DISEASES OF THE STOMACH AND BOWELS.

THERE are, perhaps, few departments of medical science which have, in the last few years, enlisted more interest than diseases known to affect the alimentary canal, and particularly the effect of therapeutics on these affections. The progress made in this direction should awaken in us the strongest feeling of pride and satisfaction, as we witness the phantom of empiricism, which has hung over the medical world for so many ages, benighting this all important field, gradually dissipating before the headlights of scientific research.

The encouraging results thus far obtained are, in a large measure, due to the aid which the introduction of chemistry and microscopy in medico-physical science has furnished clinical medicine.

Chemistry, by resolving drugs into their proximate principles, gives us light on the chemical nature and composition of the digestive ferments, and teaches us to appreciate their value when applied to the science of medicine. And, among the facts which chemistry has revealed, none are of more importance than those which relate to the unorganized ferments. Without them, life of the organism would be impossible. If chemistry thus assists us, microscopy can have no less value by pointing out their normal and pathological effects on the tissues and functions of the human economy.

Granting what we have said to be true as far as our knowledge goes, it seems to us that no department of practical medicine stands more in need of scientific guidance for its therapeutics and hygiene, than the diseases of the canal heading this paper. And while we affirm this, we do not infer that the selection of remedies suitable to individual cases, or that clinical experience and a knowledge of temperamental idiosyncrasies go for naught. On the contrary, they must enlist the physician's attention as well as any other scientific principle established. To be more than usually successful in controlling or palliating the ills of gastric and intestinal disorders, whether inorganic or otherwise, requires patient and attentive investigation of the proximate and remote effects of medicinal agents, in order to ascertain their influence in relation to systemic changes with the hope of finding out with a degree of certainty, the hidden facts regarding the relationship between the condition of the part, or parts, and the relative or absolute effect of the medicament.

A paper of this kind, to be interesting, must be characterized by brevity. Time is too valuable to be taken up with the minutiæ of the topics touched on, and if you will forbear a little, we will call your attention more to generalizations. We all know that too much attention is given to learning much that is unnecessary. Our time should be given to therapy rather than to materia medica. The therapy of foods is as essential as the therapy of drugs, and cannot be disassociated by the careful practitioner. Appreciating this, we will confine ourselves in this article to functional diseases of the stomach and bowels. Not because of the lesser importance of the other maladies attacking this tract, nor because they are better understood, but because time forbids. Practitioners are probably oftener consulted, and have their patience and ingenuity taxed to a greater degree, in dealing with this class of cases, than with any other, unless it be *hysteria*.

Under the guise of dyspepsia, we find victims of this dreaded disease in most or all climes, and in all ranks of society. It being more likely, though, to single out the high livers, and those who lead fast, irregular lives, especially if they have acquired or inherited faulty diatheses. Some authors use the term dyspepsia, interchangeably with indigestion, although the latter term more properly belongs merely to a temporary disturbed condition of the function. It matters little how used, both imply disturbances not associated with inflammatory changes. We find it pure and simple, and again we come across it associated or dependent on some other morbid condition of the body. We will speak of it as a disease, *per se*, or, when it occurs without any grave organic lesion, as a factor of production, or, when the remedies must be directed to the dyspepsia as the main source of digestive disturbance. It is a common thing to find the complainants of a highly nervous organism. Inquiry into the family history reveals, nine times out of ten, that the immediate or remote ancestry at one period of their lives suffered similarly. Possibly we have been consulted by several members of the same family, who had had good health until arriving at a certain age, when symptoms of persisting indigestion showed themselves—these patients likely leading entirely different lives; regular in habits; bodily wants fully satisfied. For such cases, hereditary transmission will suggest itself as the explanation. We stated that this disease often affected those of a highly nervous organism. Pursuing this line of inquiry still further, we observe that a large proportion of the cases applying for treatment are of a nervous temperament, and so were their forefathers. The etiology can be explained in the same way as the cases just passed—hereditary transmission.

As causes, age, deficient gastric secretion, exhaustion of the nerves of organic life, anæmia, and privation, are some of the predisposing influences. Any abnormal state of the nervous system has a strong tendency to disorder digestion. Just what relation exists between digestive disturbances and the vasomotor system is not known, nor understood. But it *is* known that injuries of certain nerve trunks will suspend, for the time being, or seriously interfere with the process of digestion. Anything directly hindering alimentation, such as excess of food, unwholesome, indigestible, improperly prepared, or imperfectly masticated food, are exciting causes

The symptoms are varied, and, to a great extent, are those found accompanying most all cases of chronic gastritis. No disease, unless it be, as I have said, hysteria, has a larger train of symptoms. Noticeable among them are a sense of fullness after meals, loss of appetite, heartburn, a whirling in the head, headache, sometimes emesis, and often abdominal pain.

The abdominal pain being due to flatulence, affecting in an unequal degree the stomach and bowels. This distension being due to the evolution of gases produced by putrefactive and pathognomonic fermentative changes of the ingesta, wrought by undue multiplication of microscopic vegetations. Fermentation taking place in those of a saccharine nature and putrefaction in those made up of albuminoid matter. The propagation of these pathogenic microorganisms, to the extent of interfering with normal digestion, goes on by virtue of altered secretion. The tongue is oftener coated with a white or yellow fur, than clean. The bowels are generally constipated, but we frequently meet with cases where it alternates with diarrhœa, especially if associated with hepatic derangement. Palpitation, depression of spirits, and dyspnœa are no unusual symptoms.

In some, when the stomach and bowels are distended, the encroachment of the diaphragm on the thoracic cavity compresses the heart, causing apprehension, gloom, and sadness, more distressing than actual pain. Attacks of dyspnœa are ushered in by a feeling of tightness across the chest, a continual desire to draw long breath and a sensation of impending suffocation. Changes in the position of the body are rapidly made, and, also, repeated attempts at inspiration, but the relief is of short duration, and the alarm and suffering intense. It is a herculean task to impress a patient so affected that his heart and lungs are not structurally diseased. The duration of attacks are varied. We have known patients to have single attacks, others to have a number, and one, who had them daily for over a month, usually coming on at night. In this person the smothering was unattended by wheezing, and he had been under treatment for dyspepsia for months before these spells came on. The paroxysms generally worked him after retiring. If asleep he was aroused by an inability to get his "wind," as he termed it. Great beads of sweat were noticeable on his face and forehead. His skin felt cool and clammy. His respiration was irregular and sighing. The action of the heart was slow and irregular. If I remember correctly, about fifty pulsations per minute. Free belching usually dissipated the attack. The physical symptoms obtained were referable to nothing else than disordered digestion. He entirely recovered, and when last heard of was working on a farm, and well.

Functional and catarrhal affections of the alimentary canal are intimately associated and the dividing line is not as clearly defined as we might wish to see it. In this monograph of functional diseases we have attempted to confine ourselves to symptoms of a non-inflammatory character, and to those readily recognized as such during life. It being often a lingering disease, it has to be differentiated from chronic catarrhal troubles, especially because symptoms exist common to both. Though in the former the symptoms are not so continuous nor so aggravated.

In dealing with the treatment, we must keep uppermost in our minds that nothing will prove curative as long as the cause remains active. It will require thoughtful investigation, and diagnostic expertness, to detect and remove the fault. Each case and special symptom must furnish its own indication for treatment. Improve the general health as much as you can, observe attentively the diet and regimen. If your patient eat too much, or too often, or if his food is unpalatable, little can be expected from drugs. The stomach must not be burdened beyond the capacity of digestion, nor beyond the absolute needs of the economy. Too protracted fasting will equally impair the digestive process. No stereotyped articles of diet will suit your cases. Individual tastes must be consulted, and the intervals of time at which nourishment is given will depend on circumstances. Some will do better when it is given at short intervals; others at longer intervals.

Now, a few words as to the effects of drugs upon the digestion. We are aware that medicines are administered in so reckless a manner as to actually produce malnutrition. Patients are often thus criminally weakened. On the strength of advertisements published—we are sorry to say—in some of our leading medical journals, remedies utterly worthless are used to the detriment of the sick.

Pathogenic microörganisms cannot be destroyed outright. Our hope for the patient lies in the strength of his cells, and measures should be taken known to foster the vital forces instead of handicapping them, and many such remedies we possess. When the appetite is impaired, hydrastin, gentian, columbo, and quinine are indicated. Should torpidity of the bowels exist, cascara sagrada, given night and morning, is a useful drug. It also serves an excellent purpose combined with ipecacuanha, nux vomica, or Berberia-aquifolium. Ipecacuanha can be advantageously associated with the mineral acids. When medicines are given that are incompatible with the gastric juice, the time of giving them is as important as the medicines. A good rule to be guided by is alkalies before meals, and acids between. Hydrochloric acid, combined with pepsin, will benefit as many cases as any remedy we know. Pepsin is only active in an acid medium, and in many instances when we are called to prescribe, the difficulty is due

as much to the lack of the necessary acid as to the want of pepsin and pancreatine.

In fevers, a less active gastric juice is secreted than normal. One less qualified for proteolytic digestion, though intensely acid as shown by litmus. These facts tend to show that the acidity is not due to the proper kind of acid, but to the presence of pathological ferments. Acetic, butyric, or lactic acid may be present, rendering the stomach juices decidedly acid, and still it may be necessary to administer hydrochloric acid to bring the acidity up to the notch most suitable for the action of pepsin.

When an antifermentative, and a digestion-promoting drug is wanted, salicylic acid should not be forgotten. Acids are indicated when the peristaltic movements of the stomach are lacking, and when the gastric mucous membrane fails to respond to the stimulus of food. Unless they be given to check the excessive formation of the acids of the gastric juice, they should be given at least an hour after meals.

Pepsin might be called the universal remedy, for resort is had to it more than to any other single remedy. It is a natural ferment and the most perfect solvent of nitrogenous food known. It will give satisfaction in feeble digestion.

Could a way be discovered to prepare pancreatin so that the acids of the stomach could not destroy it before it reached the intestines, it would be a valuable preparation in intestinal indigestion.

Fermentation is sometimes so excessive as to render patients extremely uncomfortable. In such cases sweet and starchy foods are transformed into sour, yeasty, irritating masses, which, after punishing the patients for a time, are expelled by vomiting. In cases of this kind we have had flattering results by getting our patients to sip a pint of hot water an hour before meals, thus washing out the products of fermentation, and then giving them a napthaline powder one hour after eating.

In intense cephalalgia, when the nervous system is seriously at fault, good results can be had from electricity perseveringly used. Antifebrin, phospho-caffein, phenacetine, and bromo-soda are some of the best medicines that can be given in such cases.

These observations are not conclusive, but given with the hope of eliciting interest and possibly discussion of a subject needing enlightenment.

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL.

CASE I.—Wm. M., aged thirty-three, American, by occupation a printer, complains of pain in both testicles, which are not much, if any, larger than normal, but hard to the touch. Gives a history of gonorrhœa three months ago. Diagnosis, double orchitis. Directions for treatment, paint over both testicles with tincture of iodine, full strength, twice a day, and then apply a compress of canton or woolen flannel, wrung out in hot water; cover this with another dry wrapping of wool flannel, and enclose both compresses with a pice of oiled silk, or soft, thin gum cloth or sheet, and then suspend and keep suspended the testicles in a good suspensary bag.

I have used this treatment for years, and in many cases, in private and hospital practice, with the quickest and best results.

The above noted case was quickly cured, the testicles becoming soft and free from pain in a few days, after which period the moist compress is discontinued, and only the dry wrapping and suspensory bandage or bag used.

CASE II.—J. D., aged twenty-two, laborer in iron works, robust and healthy in appearance, presents himself with a healthy looking incised wound, of large size, on the palmar surface of the right hand. Patient was cut by a heavy piece of steel, and was first attended at the Charity Hospital, when, after antiseptic cleansing and several stitches had been put in, he was referred to this clinic.

As the patient's wound is healing kindly, it is only necessary to carefully work in hot antiseptic solution of corrosive sublimate, 1 to 2000, dry and powder with iodoform, covering with a gauze of the same.

CASE III.—P. J. S., aged forty-two, a laborer, presents himself with a chronic, sluggish, ill-conditioned abscess of one cheek. The patient presents the appearance "strumous," as evidenced by pallor, glandular enlargements, etc., and the character of the pus is thin and sanious. The indications are plainly to build up by tonics and alteratives, both systemic and local. We order, therefore, the use of the muriated tincture of iron, internally, and the iodide of potash, and after freely opening the abscess at the most dependent portion, we cleanse with the hot 1 to 2000 corrosive sublimate wash; inject, with full strength, tincture of iodine, insert drainage-tube of clean antiseptic gum, cut off to the length of one inch external to the opening, and then apply some iodoform gauze loosely about the gum to catch all discharge.

By careful attention to this line of treatment I shall expect a good result. I have carefully enquired of the patient as to specific disease in the past, and do not learn of any. If the patient does not thrive under this treatment, it may be necessary to change to still other alterative treatment; but let us bear in mind that in all these cases we must not forget to put the patient on good nutritious, special diet, not forgetting a free use of good fibrin-producing food, such as milk and the various animal foods.

NOTE.—Each of the above-noted cases healed soundly, but the latter required much longer time and more careful attention to antiseptic and alterative measures.—*Stubbs.*

VACCINATION.

The virus from children is milder than that from animals. As the virus is used from child to child, it grows weaker.

Inefective Virus.—Two varities were noticed. First, from arms previously vaccinated. Second virus taken too late in the vaccination.

There is only one real danger from vaccination, and that is syphilis. Impetigo is contagious and sometimes results from vaccination but is easily cured. The same may be said of chicken pox.

If a patient is of a scrofulous diathesis it is apt to develop.

Do not vaccinate during febrile indications.

Virus may be removed on the sixth day, but the lymph will not keep.

On the fifteenth day remove the scab and always wipe off the pus.

If any pus has been allowed to remain it must be removed before using the crust, the first vaccination should be made at three months of age, and the second at the seventh year.

Three children were shown who were vaccinated at one of the previous clinics showing arms sore on the eleventh day, which was unusual as the ninth day was the general limit.

The virus had escaped from these crusts rendering them inert, and the use of such crusts would account for some of the failures. A sore did not always indicate a good "take." After healing it must present a deep pitted appearance as in smallpox, otherwise the prophylaxis is not assured.

WHOOPING-COUGH.

Various remedies have been tried and found wanting. Bromide of potassium, cyanide of potassium, monobromated camphor; the old-fashioned cochineal mixture etc., etc. A more recent remedy was fumigation by burning sulphur in a close room.

Three hundred and eighty-five grains of sulphur to every cubic foot yard of air space is the rule. The clothing and bedding is also to be fumigated. This method of treatment had failed in his practice. Quinine in three or four-grain doses in solution injected into the throat had effected a cure. The most effective remedy was the inhalation of illuminating gas, but during the first stage of the disease treat it as an ordinary catarrh. Keep a tally-book for the whoops, as only in this way could any change be determined.

For the case before the clinic he ordered two mixtures, one was the elixir of quinine and iron and the other cod-liver oil and syrup of orange peel simply shaken together. He preferred this to an emulsion.

PAIN OVER THE RIGHT EYE.

In the case of a man suffering with pain over the right eye he called attention to the necessity of a careful diagnosis between a true neuralgia and the so-called brow ague, which was a reflex pain due to liver derangements, etc. This patient, however, was referred to the eye department, as the trouble seemed to lie in that direction.

DISEASES OF THE STOMACH.

In commenting upon a case diagnosed as atonic dyspepsia Prof. Waugh briefly outlined three principal diseases of the stomach, viz.:

1. Gastric ulcer, a disease of young women.
2. Carcinoma, a disease of old men.
3. Catarrh of the stomach, the most common of all the ailments. For the atonic dyspepsia he ordered a restricted diet and pepsin, muriatic acid and tincture of nux vomica.—*Waugh.*

CONSUMPTION.

Prof. Woodbury presented a man complaining of spitting of blood and a cough. The patient is fifty years of age. He attributes his malady to sleeping in a room filled with coal gas.

The lungs upon auscultation give submucous rales showing softening. His hands are quite warm, but the temperature is only ninety nine and one-half. The fever of consumptives is treated by rest, also by ice. The yolk of eggs was recommended as a food, and as a sedative the bromide of sodium or ammonium in preference to potassium, as the latter depresses the heart, already weakened by disease. The skin should be brought into healthy action.

Consumption begins in a catarrhal condition.

—*Woodbury.*

ALBUMINURIA IN PREGNANCY.

Prof. Stewart in commenting upon a case of albuminuria in pregnancy, said that about twenty per cent. of all patients suffer from this ailment during this period. It is generally temporary, coming on during the latter months of the term, although it may have existed previously. It is caused by the pressure of the gravid uterus upon the renal veins, and extra work is thrown on the kidneys.

Always test for albumen in pregnant patients and meet the indications promptly so as to avoid convulsions later on As to remedies, colchicum and saline cathartics were recommended. For the convulsions following such cases he had found nothing so effectual as injecting chloral hydrate into the rectum.

—*Stewart.*

REMOVAL OF CYSTIC TUMOR.

Prof. Montgomery, before the removal of a cystic tumor, pointed out the difference between such growths and true fibroids. The fibrous cysts are not so frequently met with as the true fibroid tumor.

In these cysts we find a fluid resembling liquor sanguinis. They generally result from a degeneration of a fibrous tumor, the bloodvessels of the latter breaking down and a cyst is formed.

Some called them lymph spaces. The symptoms are the same as in true fibroid. They are generally found outside of the uterus. Simms emptied one, disinfected it, injected iodine and destroyed it.

These cysts may be mistaken for a pregnancy. They are, however, not uniform like a pregnancy, but are nodulated. They do not stop the menses; on the contrary, rather aggravate them. They are fluctuating and elastic. They are differentiated from ovarian tumors by being smaller and slower in growth. Another method was to tap the cyst and ascertain its character. Drysdale thought that there was a peculiar cell found only in ovarian tumors, although this has not been fully proven.

Fibrous cysts grow to a large size, and continue for a long time. They do not, like a true fibroid, sometimes subside without operative interference.

In speaking of polypi, he said we must not class them with tumors resulting from parts of a placenta left in the uterus. Polypi may be cellular, mucous, or fibrous. They are developed more particularly in the body of the organ. They may be multiplied, and

look like a bunch of grapes. These tumors gave rise to dysmenorrhœa, leucorrhœa, pain in the back, etc.
—*Montgomery.*

OPERATION FOR CATARRH.

Prof. Keyser, before operating for cataract, called attention to some serious complications that might arise. If the patient is suffering from albuminaria or diabetes, the cornea will slough. If the iris will not contract quickly, do not operate, but make an iridectomy, and wait six or eight weeks before operating. In all cases ask the patient whether flesh wounds heal readily or not. If they do, the operation will be a success.

In examining for cataract do so by an oblique light, or by moving a lighted candle in different directions before the eye or eyes as the case may be, as it would be useless to operate upon a "blind" eye, or where the fault was in the retina as well as in the lens. A traumatic cataract is apt to cause glaucoma.

A case of glaucoma was shown, and the following prominent features of this obstinate affection pointed out:

1. Increase of tension of the ball.
2. Rapid presbyopia.
3. Dilated ciliaries—sausage shaped.
4. Arterial pulsation.
5. Cloudiness of the aqueous and vitreous humors.
6. Dilatation of, and sluggishness of the pupil.
7. Periodic dimness of vision.
8. Halo about a flame or rainbow colors seen.
9. Ciliary neuralgia; which is very important.
10. Field of vision contracted.

Glaucoma is a disease of old age. It always attacks one eye and may remain in one only, but the other is liable to become affected.

In examining old eyes use atropia cautiously, as if there should be a latent glaucoma, *i. e.*, an increase of tension, it might be lighted up. Use eserine, one to two grains to the ounce of water, but even this must be carefully administered or it will set up an irritis.

For inflammation of the cornea, Prof. Keyser ordered the following:

R.—Iodoform . . . . . gr. iij.
Lanolin vel adipis benzin . . . . gr. j.
M.—Sig. Apply to the cornea as directed.

Cocaine should not be used in inflammations of the cornea, as it depletes nutrition, and not only fails to relieve, but is a positive injury.—*Keyser.*

PENNSYLVANIA HOSPITAL.

IN lieu of a clinic, Hunt made a few remarks on "railway spine." Shock he defined as that combination of symptoms brought about by a sudden depression of the nervous system. Page, he said, does not believe in transitory shock, and for that reason declares that there is no such thing as railway or spinal shocks. But to prove that a transitory shock does occur, Hunt cited a case in his own practice as clearly demonstrating it. It was the case of a man who had fallen from a considerable height on his feet, breaking the os calcis of each foot, which was followed by complete paraplegia of lower two-thirds of trunk and lower extremities, but terminated in an entire recovery. In the space of five years, he said, after Erichsen had published his investigations on spinal shock as produced by railway travel, English railway companies paid $11,000,000 in damages, suits for which were based on the authority of that eminent surgeon.

In cuneiform operations where a wedge of bone is removed, Ashhurst does not favor the use of a fixed plaster dressing. In fractures, however, he does, but does not apply it until after the callus is formed and the patient is able to go about.

TYPHOID FEVER.

The patient before us is a young man, printer by trade, admitted into the hospital a week ago, suffering from typhoid fever. On admission his face was flushed, tongue furred, tremulous and red along the edges. His abdomen was full, tympanitic and covered with red colored spots; temperature 103°, bowels loose, fæces yellow. He was troubled with a cough, a result of imperfect respiration produced by an over-distended abdomen pressing on the diaphragm, thereby interfering with proper aëration of the lungs. While I ask this patient to sit up that I may examine his lungs, I, as a rule, avoid having my patients do so, as they are more or less liable to faint when in that position, owing to the additional work it imposes on an already much weakened heart. In examining the spots on the abdomen it is necessary to differentiate them from acne spots. The rose-colored spots of typhoid fade away upon pressure and present no rough points to the touch as do the spots of acne. This patient we have kept under the regulation treatment, and is doing as well as can be expected.—*Longstreth.*

ACUTE ENTERITIS.

This patient has been ill three weeks. Has had from three to six movements a day, for which he can ascribe no cause, having always been healthy and temperate. Upon admission to hospital he was languid and pinched in appearance, tongue glazed and red all over, though uncoated. His temperature was 102°. His treatment consists chiefly in the regulation of his diet. He is given only such food as is not irritating, such as milk and soup, and a few spoonfuls of corn starch to give more consistency to his stools. He was given large doses of bismuth, thirty grains, every three hours, continued for three days, until stools were reduced in number. Fearing a typhoid condition, quinine and hydrochloric acid were given. A denuding of the mucous membrane of the intestinal tract is productive of more intestinal indigestion than any other cause, and is a condition very difficult to cure, inasmuch as the mucus which is being thrown out mixes with the food, and with it undergoes fermentation, whereby a constant source of irritation is maintained. The continual passage of the food through the intestinal tract does not give the mucous membrane time to repair itself.
—*Longstreth.*

PUBLIC BATHS.

AS in modern statesmanship, the great problem is the attainment of "the greatest good to the largest number," so it is the aim of modern medicine to achieve the same end by the prevention rather than by the cure of disease.

The study and practice of sanitary medicine, illumined as they are by marvellous discoveries in the sciences and arts, attract the best minds in our profession, because of the brilliant possibilities of this interesting field.

The improved sanitary condition of the civilized world, chiefly evidenced by the absence of those terrific epidemics which formerly scourged the most populous countries, has long been our boast. Nevertheless, the civilized world is far behind former ages in one great essential of sanitation—personal cleanliness.

Startling as this proposition may seem, it is open to absolute demonstration by historical data, as is clearly shown in a recent address of Dr. Lassar.

The recognition of the vital importance of personal cleanliness may be traced into the remotest antiquity. Zoroaster and Moses made it a law whose infringement was severely punished, and indeed, all Asian and Semitic nations had it impressed upon them by their ceremonial acts. These facts are so well known that they need only to be referred to here.

In the latter centuries before Christ, bath-houses were introduced from Greece into the smallest Italian towns, not only for ordinary use, but many were erected on the most luxurious scale. Seneca tells us that the walls of some of these establishments were covered with mirrors, and the floors with Numidian marble; the basins, surrounded by rare stones, received water from silver faucets; magnificent statues and pillars abounded, and the water fell in immense quantities in cascades upon the bather, whose eye meanwhile rested upon the most ravishing landscapes, exposed to view through the spacious windows.

Vispanus Agrippa built one hundred and seventy free baths in one year. Others were offered to those who were able to pay, for the price equivalent to one cent of our present currency. Nearly every well-to-do householder had his own private bath. From the time of Augustus to that of Constantine fourteen hot baths were erected, each one of which accommodated thousands of bathers. In Rome alone there existed, during the residence of Constantine in Byzantium, eight hundred and fifty-six free baths, which consumed seven hundred and fifty million gallons of water.

Pliny asserts that for six hundred years the people of Rome needed no physicians, because they bathed.

These grand structures, however, fell under the savage destruction of the uncultured multitudes which crushed out the power of Rome, and trampled upon its great works of art. The world has not yet recovered from the effect of this invasion of the field of hygiene.

To-day the paradox exists that among people whom we are wont to regard as uncultured, the resort to water for personal cleanliness is more in vogue than it is in our midst.

In Russia the poorest peasant would not don his holiday attire, without resorting to his village bath. In Japan hot baths are accessible to the people in the very humblest villages.

This glaring defect in our boasted civilization has been again and again recognized, and the press, that most potent agitator of the rights of the people has struck sledge-hammer blows in behalf of public baths. The New York *World* not long ago published a series of well written articles upon this subject, which have borne some fruit. It is to be hoped that this sturdy advocate of the people's prerogatives will again be heard from in the good cause and induce other journals to follow its energetic and brilliant initiative.

The interests of good sanitation demand constant and unceasing agitation of the subject of public baths. The family physician, armed with the historical facts briefly enumerated and imbued with the consciousness that cleanliness of person among the lower classes will surely tend to check epidemic diseases at the very portals of its usual entrance, may contribute vastly to the dissemination of ideas that will surely bring valuable practical results.

If public baths could be made as accessible as they were in the palmy days of Rome and Greece, the health and happiness of the laboring classes would be greatly enhanced; the unrest and discontent, which are but the muttering of a storm that will sooner or later sweep with devastating fury over our prosperous land, would be allayed by the recognition of the fact that they whom fortune has favored bear a kindly interest in those who are tottering under the heavy burden of poverty and its inevitable train, misery, and death.

A feeble step in the right direction has already been taken by the public baths which some of our cities offer during the summer months. But the number of these baths is ridiculously small, and they are entirely absent during the winter months when they are most urgently needed.

Lack of water and room, and the large expenditure of money required, offer the most potent obstacles to the extension of public baths. All these obstacles may be readily surmounted by the adoption of the rain and douche baths, which have been successfully utilized in the German army and in several large German cities. These baths are simply arranged, built in the most economical, yet substantial manner, and divided into spaces just large enough for an adult to stand and move comfortably in. The bather bathes himself with soap, and turns on the cold or warm water, which falls upon him as a spray or douche. The mechanical action of the stream, aided by his own efforts, rapidly cleanses the body, and the water flows away over the latticed flow into a receptacle, which conveys it to the water pipes. The time, consumption of water, and attendance are thus reduced to a minimum; cleanliness of the bathing-room is readily obtained, and the danger of contagion, which would deter many from resorting to tub baths, is entirely obviated.

Simple douche baths of warm soap-water should be attached to our public schools, and the afternoon hours should be devoted to the task of cleansing the bodies of the little ones. The warm soap douche would be a great boon to the poorer and laboring classes in midwinter, when they rarely, if ever, have an opportunity, owing to the narrow limits of their dwellings to cleanse their bodies. To the middle classes the cheapness of such a bath would commend itself. The construction of a few warm and douche baths in our large cities would popularize bathing and protect the community against many diseases, without a large outlay of the people's money.

CHLORAL HYDRATE IN SEVERE CHOREA.

FOR the ordinary choreas arsenic is still the remedy par excellence, but now and then one comes across a case of old, long-standing, or severe chorea, which resists every known means of medication. With such cases many new and novel methods of treatment have been instituted for a time, but usually they have ended in failure. Only rarely forced rest and seclusion have cured the disease, as in cases reported by Van Bibber, of Baltimore. But not often does it happen that prolonged sleep, and especially sleep produced by chloral hydrate, terminate in a permanent cure, as in Dr. Gairdner's well-known case (Glasgow *Medical Journal*, new series, Vol. II, 1869–70, page 550), which was accidentally given sixty grains of chloral with the happiest results, and in the case reported by Bouchut (*Bulletin Générale de Thérapeutique*, February, 1873), in which forty-five grains of chloral a day were given for twenty-seven days with a complete cure of the chorea and dementia on the twenty-eighth day of the use of the chloral. In these cases the seat of the trouble itself seems to have been favorably affected. There may have been a certain amount of habit in both instances which was removed by the profound impression caused by the narcotic. But it is difficult to imagine that the drug affected primarily in any way the diseased centres in view of the many other cases in which cessation of the movements could only be obtained during the artificial sleep. Why this artificially produced and prolonged sleep should result in a complete cure in some instances and in nothing at all save the artificially produced periods of rest in others cannot be explained until we know more about the pathology of chorea. Neither Bastian's experience (*Lancet*, July 13), Bouchut's nor Gairdner's (*Lancet*, August 3), would at all lead to the idea that chloral in itself was in any way a specific for chorea, hence the rest itself was the curative agent.

Cases have been reported in which benefit was obtained by interpolated long periods of sleep, of a certain number of hours or days, it not having been considered safe to continue the sleep as long as Bouchut had done. In two of Dr. Gairdner's cases, recently reported (*Lancet*, August 3, 1889), one still under observation, the other having died from exhaustion, which was pronounced before beginning the chloral treatment, the good effects of the treatment seems to have been clearly indicated. In one of them the au-

thor saw such an improvement as to lead him to dissent somewhat from the assertion of Bastian that "in the most acute and severe cases of chorea, in which the temperature is raised and the movements are violent and continuous, with or without delirium or maniacal symptoms, I have never yet tried this mode of treatment *and should not recommend its adoption.*" Chorea is a disease that usually proceeds from bad to worse, and hastens its over development by exhausting the general constitution. The uncontrollable jactitations so disorganize and disarrange the other functions of the body that decline and death occur as the result of the latter rather than of the chorea. Reason dictates, therefore, that in these intractable cases the best hope of a cure is to be based only upon frequent periods of rest prolonged as much as the safety of the patient and freedom from symptoms of poisoning will allow. The chloral treatment of severe cases of chorea has given results far from what would be desirable, yet sufficiently favorable to warrant longer and closer study.

A SOCIAL EVIL.

ONE of the blessings and curses of modern civilization is the piano forte. With the invention of the instrument began a new era in the matter of musical entertainment, and since then it has risen into such popularity as to leave its many competitors far in the rear. No house is thought to be completely furnished nowadays where there is not a piano, and hence it is heard everywhere and at all times. Occasionally its tones are soft and soothing, more often they are rattling and torturing. We have often wondered how it was that an instrument which is considered second in difficulty only to the violin for its complete mastery ever became so popular. Could any one be so malicious as to continually rack the ears of his neighbors with amateur efforts upon a cracked violin, or howling cornet, even did these instruments "furnish the parlor so well" as the piano. But we have wondered still more often how it was that girls were so universally obliged to study the piano. The first daughter born into the family is destined from the moment that the sunlight first sparkles in her eyes to be put at the study of music as soon as possible, and often long before she has acquired the slightest knowledge of anything else. Perhaps she exhibits no taste whatever for the art, but then she's a daughter, and along with her younger sisters must continue day after day thumping her patience, amiability, and health away trying to learn what fashion has considered *proper* for her to know. A recent German writer has attributed a large part of the nervousness among young girls to their piano forte practising, and the matter is receiving at present much consideration from the London physicians. Nothing is more absurd than to compel a delicate, nervous girl to practise and practise, ofttimes six and eight hours a day, the same monotonous exercises merely to humor a fashionable whim. There is nothing in its favor when the disposition is vigorously opposed to it; for it certainly does not develop grace either of body or movement, nor does it bespeak special culture more than any other more congenial art would.

The long hours of practice indulged in by those who are fond of it are not only dangerous, but frequently unnecessary. The habit is one that grows, and the emotional nature is so stimulated that the performer is restless unless she is practising. We know of most admirable pianists — certainly — who could entertain the most cultured non-professional audiences that have never practised more than a couple of hours a day. Regularity of time well distributed does more than length of hours.

As we have also said, the emotional nature becomes overstimulated, and thus the equilibrium necessary to the preservation of the nervous health is destroyed, and all sorts of nervous ailments ensue. This is readily confirmed by the lives of most of the great composers and pianists of the world.

It is time, then, that physicians should take this question into consideration and educate people out of the silly notion that every girl must be a pianist. Away with the absurd fashion, and many of our girls will be more healthful, will enjoy life with a keener zest, and many of the common ailments now arising from an overwrought nervous system will disappear.

Furthemore, our ears will be less tortured by the rattling noise of ancient pianos thumped by dispirited unmusical amateurs. It is the physician's duty to correct this evil, and to him we make the appeal for the benefit of music-loving ears and delicately organized nerves.

AN ERROR OF SPECIALISM.

"SPECIALISM" of a certain sort has again put itself into a ridiculous attitude before the medical world, for there has just been issued in London a classified list of practitioners who chiefly attend to special departments of medicine and surgery in that city, with particulars of the principal special hospitals and special departments in general hospitals, edited by W. P. W. Phillimore, M.A., B.C.L., Queen's College, Oxford. This together with the many other useless and hashed up compilations now being published upon all sorts of medical matters remind us of the old truth that "there is no end of making books." In commenting upon the present volume the editor of the *Lancet* says: "Concerning the most eminent persons the information is least, concerning the less distinguished it is 'special,' and would almost suggest the profane thought that it has been self-supplied. Can anything be more ridiculous than to suggest to medical men that they need a lawyer to tell them the persons to consult in a given case of difficulty." Sir Andrew Clark "who is too great to be belittled and too general to be specialized," is here set down as a specialist for chil-

dren, is daubed *great* in regard to the eye and *specially* commended for consultation in cases of midwifery and diseases of women and children. The absurdity speaks for itself, and yet it but indicates one of the evils of specialism.

A PERSONAL JOURNAL.

WHEN the *Medical and Surgical Reporter* has retracted its previous misstatements concerning this journal and its editor, and apologized for the same, we may notice its later statements. Until this has been done we do not consider it worth replying to. Its readers may be willing to pay for the privilege of being informed as to its editor's opinion of us, but ours prefer that we shall devote our space to matters medical.

Annotations.

AIMS AND LIMITS OF HYDROTHERAPY.

THE application of water in any form, at any temperature, externally or internally, without admixture of medicinal agents, is the province of this special branch of therapeutics.

It is not an infrequent error to regard the external application of cold water, or its combination with cold water drinking, as in the so-called water cure, as the only aim of hydrotherapy.

The modern application of the term, on the contrary, embraces every method by which pure and unadulterated water is utilized in the prevention and treatment of disease. As we have insisted in a previous article (DIETETIC GAZETTE for April, 1889), the surgical use of hot water for purposes of asepsis, the gynæcological application for the treatment of piloric inflammation, its internal use in gastric derangements, the need of tepid temperature in intestinal diseases, all these belong to the field of hydrotherapeutics, because they each depend upon the effect of temperature and mechanical results of water alone.

The successful application of ice (frozen water) in cardiac, nervous, and inflammatory affections furnishes another illustration of the value of modern hydrotherapy.

In our discussions of this subject in future numbers of THE TIMES AND REGISTER, we do not propose to confine ourselves to the external and internal use of cold water, as is the practice of the hydropaths, but to expand into a broader and more fruitful field, whose limitations shall be that water in some shape is the single agent applied in the treatment.

DR. S. LUSTEGARTEN.

OCCASIONALLY one of our trans-atlantic confrères actuated by the conviction that his mission would be best fulfilled in our country, emigrates to our shores, bringing with him a record of brilliant attainments which at once assures him a steady position in our midst. Dr. H. Knapp presents an illustration of such a career.

At the present time we are pleased to record an event which is regretfully referred to by the *Wiener Medicinische Presse* (July 28, 1889), as follows: "A few days ago a most promising young physician of Vienna left his native city in order to find a new home on the other side of the ocean. Docent Dr. Lustegarten, one of the most able of the younger workers in syphiology and dermatology at our university, which have emanated from the school of Kaposi, a man who is most favorably known through his numerous original works, is on his way to the new world. We will not discuss the causes which tear this promising man of learning away from his friends, colleagues, students and patients, but desire to express our sincere regret for the loss of this man and we hope that Lustgarten may find a new field of satisfactory scientific and medical activity in his distant home."

Dr. Lustgarten is well known as a teacher to the numerous Americans who have resorted to the great Vienna School of Dermatology in recent years.

He studied leprosy under Asmanen Hausen, in Beyen, Norway, and visited many other parts of the world in the pursuit of his studies.

His greatest achievement is the discovery of the bacilli of syphilis in 1885.

We welcome this active and original worker in our midst and bespeak for him a hospitable reception.

RECENT DISCOVERIES IN MORPHINE, STRYCHNINE ELIMINATION.

DR. ALT (*Berl. klin. Wochenschrift*) has demonstrated by experiments on dogs and confirmed the latter in man, that morphine injected subcutaneously is eliminated by the stomach within an hour, and that this elimination is the cause of nausea, which may be relieved by stomach irrigation. At least one-half of the morphine injected may be recovered from the stomach by the irrigation; and toxic symptoms produced by subcutaneous poisoning may be removed by the latter. The importance of this discovery in medico-legal examinations and in morphine poisoning is evident. In the former case evidences of the presence of morphine may be obtained in the stomach, and in the latter the effect may be neutralized by irrigation. Thus the hopelessness of accomplishing either one of these important results after subcutaneous injections may be abandoned.

Elimination of Strychnine.—From actual experiments on frogs Dr. Lovett (*Journal of Physiology*) discovered the important fact that the larger proportion of strychnine is stored up in the spinal cord, in which he found more than in the brain, liver, stomach and muscles together. This is an important medico-legal point, because it emphasizes the necessity of examining the spinal cord as well as the stomach in cases of suspected strychnine poisoning.

Treatment of Insomnia.—Jastrowitz read before the Society for Internal Medicine a paper on this subject, in which he concludes that morphine and opium are indicated in acute cases, especially in the anæmic, for the removal of apprehension and pain. In depressed heart action and in congestions special precaution is necessary.

Paraldehyde is recommended for acute forms of insomnia, especially in heart affections, while in chronic cases it must not be long continued, a change of remedies is specially advisable.

Amylhydrate may be given in acute as well as in chronic forms of insomnia, especially when the stomach is deranged.

Sulfonal is adapted for acute cases, when it is not important to be prompt and in all chronic cases of insomnia.

It should always be the aim of the physician to discover the cause and remove it in order to equalize the nervous organism.

Sulphur in Rheumatic Arthritis and Muscular Rheumatism.—Sir Alfred Garard in bringing this ancient remedy forward, claims that small doses frequently repeated are followed by the best results when combined with minute doses of cream of tartar. He also recommends the combination in torpor of the liver, in hemorrhoids, constipation, and in some skin affections.

A CONTRAINDICATION OF ANTIPYRIN.—Antipyrin (London *Medical Press*), among its other properties, exerts a hemostatic effect, which, according to Dr. Huchard, may be productive of serious results if incautiously given during a menstrual period. He mentions a case of woman suffering from severe dysmenorrhœa, for whom he ordered sixteen grains of the drug, with the effect of immediately suspending the flow. The arrest was accompanied by shivering and cyanosis and a tendency to syncope. These symptoms caused him a great deal of anxiety for half an hour, when they gradually passed off. He has noticed the same effect, but less marked, in two other cases in which he had prescribed the drug under similar circumstances.—Memphis *Medical Monthly*.

Book Reviews.

INEBRIETY, ITS ETIOLOGY, PATHOLOGY, TREATMENT, AND JURISPRUDENCE. By NORMAN KERR, M.D., F.L.S. Second edition. London: H. K. Lewis, 1889.

This is the second edition, with careful revision and additions, of a work which has already received a hearty welcome from the profession. It is one of the evidences of medical progress that narcomania, whatever may be the poisonous agent, is recognized as a true disease, and thereby treated otherwise than as a crime. Yet its causation is so frequently dependent upon the will of the patient, that the latter has often been deprived of merited sympathy, and the condition overlooked as one of a pathological character. No physician of the present day can afford to be unacquainted with the least of the details of this disease. Hence the present volume, which is an exhaustive study of the subject by one who has devoted much time to its investigation, should receive a wide circulation. In twenty-three chapters, the author has minutely, yet concisely, portrayed the nature of the disease, its etiology, and varieties, pathology, treatment, and medico legal aspects, giving the reader the very latest views as the result of a close study of the literature of the subject and of his own wide experience in this special department of medicine. The indexes, both at the end and along the margins of the body of the work, recommend it also as a convenient reference and text-book. It is not necessary to quote further from the work itself, as the first edition has already been some time before the medical world.

TRANSACTIONS OF THE SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION, Vol. I. Session of 1888, Birmingham, December 4 to 6. Birmingham: Caldwell Printing Co., 1889.

Judging alone from this first volume of published transactions, this Association is in a most flourishing condition and doing valuable work. Besides the annual oration, there are twenty-eight papers; many of them of decided merit, and upon the most recent and practical themes. Without specifying we will note that they treat of brain surgery, antisepsis, laparotomy, electrolysis, cystoscopic examinations, various gynæcological operations, besides reports of many interesting cases. None of the discussions have been included, though we infer from the notice of the Committee of Publication that they will be in the next year's report. The type is open and clear, the paper moderately good, and the binding strong and attractive.

CHEMICAL EXPERIMENTS FOR MEDICAL STUDENTS ARRANGED AFTER BEILSTEIN. By W. S. CHRISTOPHER, M.D., Demonstrator of Chemistry, Medical College of Ohio. Cincinnati: Robert Clarke & Co., 1888.

For the purpose of familiarizing the medical student with chemical manipulations this small book answers very well, but it is by far too condensed to be of any use as a guide to the study of chemistry, however elementary. In his preface the author says "the object has been to simplify and limit, rather than to multiply, the number of experiments." The topics relating to physiological chemistry and urinalysis have been very judiciously made more important than those of inorganic chemistry. While brief compilations of this sort are desirable as reference books for the laboratory and note-books for the lecture-room, we must again caution students against hoping to acquire from them the perfect knowledge only to be obtained from the larger manuals.

A LABORATORY GUIDE IN URINALYSIS AND TOXICOLOGY. By R. A. WITTHAUS, A.M., M.D., Professor of Chemistry and Physics in Medical Department University of the city of New York. Second edition. New York: William Wood & Co., 1889.

It is scarcely necessary for us to do more than merely call the attention of our readers to this excellent little handbook, as this is its second edition and the title fully explains its purpose and scope. The plan of the work is concise and well adapted for a lecture-room note-book. The illustrations are numerous and well selected. We are pleased to commend it to practitioners, and especially to students, as a correct and convenient guide to the study of physiological chemistry.

The Medical Digest.

PARALDEHYDE AND SULPHONAL.—Dr. C. M. Hay (*American Journal of the Medical Sciences*) arrives at the following conclusions:

1. That paraldehyde is the safest hypnotic where a continuous action is desired.

2. That paraldehyde has a wider range of application in mental diseases than sulphonal, and that in the insomnia of acute or chronic disease, where pain, cough, dyspnœa, or fever exists, sulphonal is less effectual than paraldehyde.

3. That in all depressed mental states sulphonal acts ineffectively, and acute melancholia should be a contra-indication to its use, while in maniacal conditions it is more satisfactory than paraldehyde. That the use of the former in general paralysis in the insane should be carefully considered, while in acute melancholia the latter is usually effective.

4. That a high degree of physical debility with insomnia should contra-indicate sulphonal.

5. That in 18 per cent. of cases various degrees of sulphonal intoxication appear, and that it would seem that the drug is capable of being dangerous to life, and that, therefore, the commencing doses should be small, some persons being extremely sensitive to its influence.

6. That the effects produced by sulphonal are not always in proportion to the dose administered, and that in some cases at least it very seriously interferes with the normal bodily secretions, while paraldehyde does so to a very much less extent.

RENAL COMPLICATIONS IN WHOOPING-COUGH.—Some time ago Dr. Stefano Mircoli pointed out that he had several times observed renal complications in whooping-cough. Thus, on one occasion, among ten children suffering from the disease, nephritis occurred in two cases, one of which died. The necropsy left no doubt as to the existence of the renal affection. During another outbreak, among thirty-five cases nephritis developed in four. Two of these died, and in one a post-mortem examination was made. The kidneys were examined microscopically, and were seen to be in a condition of severe parenchymatous nephritis. No microörganisms could be seen. Recently Dr. Mircoli has brought forward additional evidence on the subject. In a recent epidemic at Monterrubbiano, of twenty-four patients, three died, one from suppression of urine, another from suffocation in a paroxysm of coughing, and a third from marasmus. In the two latter cases, although during life there were no symptoms of renal affection, on post-mortem examination venous stasis in the kidneys with commencing albuminuria was found. There was also a considerable amount of hemorrhagic infiltration. Cultures of the kidney tissues gave negative results. Dr. Mircoli believes that the renal affection is due to venous stasis caused by obstruction of the vena cava through the violent paroxysms of coughing. According to him the kidney is affected, in whooping-cough, in 12 per cent. of cases occurring in children.—*London Medical Recorder.*

ON THE INFLUENCE OF PERMANGANATE OF POTASSIUM ON MENSTRUATION. — Prof. Stephenson gives, in an interesting article, the results obtained from a series of observations extending over a period of three years upon the value of potassium permanganate in the menstrual diseases. During this time he has collected one hundred and five cases in which reliable results were obtained. In his investigations he exhibited the drug in the form of a pill containing two grains of permanganate in sufficient kaolin ointment, one pill to be taken after meals. In a few cases this dose was doubled. In stating the results obtained he says: "It is evident that in the permanganate of potassium we have a remedy which has a considerable influence upon the function of menstruation when that function is deranged. In the matter of time, it tends to promote the normal periodicity both when the periods are too long and when too soon. It aids in restoring the menstrual flow when suppressed, to increase it when scanty, and to moderate it when in excess. It relieves much of the menstrual suffering, has a direct influence on some forms of ovarian pain and the headaches of menstrual origin. It has a remarkable influence in checking leucorrhœa."

In conclusion, he infers that the direct action of the drug is upon the vaso-motor center, especially those regulating the generative system.

—*British Medical Journal*, July 20.

NUTRITIVE VALUE OF BLOOD.—Dr. William Hunter, in the first of a series of these lectures on Transfusion: its physiology, pathology, and practice, says that the results of the observation of various investigators upon the blood of persons who had been subjected for some time to starvation go far to prove that the blood is not the "nutritive fluid of the tissues" as it has been called, and that "to tranfuse blood on account of any nutritive properties it may be supposed to possess is an operation entirely devoid of any physiological basis." From his studies of the behavior of the blood in health and disease, he arrives at the following conclusions:

1. That the blood is in all respects a living tissue of highly specialized structure, adapted for the performance of certain specialized functions—namely, the conveyance of food material, gaseous and solid, to all the tissues of the body.

2. That it possesses, in common with all tissues, the power which this characteristic feature of living tissue—namely, of maintaining a certain physical structure and a certain chemical composition in the presence of the most varying physical condition.

3. That the peculiar fluid nature of its matrix necessited in its case special arrangements for the regulation of its composition not required by the other tissues.

4. That this mechanism is to be found partly in itself—its white corpuscles and the endothelium of its capillary walls—partly in certain organs in specially close relation to the blood—namely, gastro-intestinal mucous membrane, more especially the follicular tissue around the portal radicles, the spleen, liver, bone-marrow, and lymphatic glands.

—*British Medical Journal*, July 20.

ONE YEAR OF ACETANELIDE.—In a paper entitled One Year of Acetanelide in Pediatric Practice, read before the last meeting of the American Medical Association, Dr. I. N. Love says:

"After more than eighteen months experience in the use of acetanelide for many of the febrile spasmodic and painful disturbances of childhood, a record of its use upon six hundred children kept for purposes of comparison with past experiences with other drugs for similar conditions, I feel justified in arriving at the following conclusions:

"1. Acetanelide, carefully guarded and properly used, is a safe and reliable remedy in the diseases of infancy and childhood.

"2. Whether used for the antipyretic, analgesic, or sedative effect, it is preferable to antipyrin in that the result secured is of longer continuance and the depression is not so great.

"3. The cyanosis which sometimes results from its liberal use is not uniform, and while it is not an agreeable feature, my experience corroborates that of other observers to the effect that it soon passes off and is not accompanied by danger.

"4. It is not desirable in reducing temperature, no matter what means be employed, to use them in excess to the extent of securing sudden and great reduction. Especially is it preferable in using acetanelide for antipyretic purposes to give it in medium doses to the extent of keeping the temperature down to a reasonable point, in the neighborhood of 100° F. It is better to give small doses and repeat them more frequently, rather than large ones at long intervals.

"5. After having used acetanelide during a period of eighteen months, and having administered it to not less than 1000 children, I feel free to say that it is a valuable aid in the treatment of the diseases of children. In no instance have I had occasion to regret its use.

"6. It is of great value as a controller of temperature in the various fevers, whether they be caused by the typhoid germ, malaria, or the exanthemata.

"7. It serves almost as a specific in whooping-cough, not in aborting the disease, as it has a definite course to run, but in mitigating the discomforts and controlling the paroxysms of the same.

"8. Acetanelide, while of great value, and surely safer than antipyrin, is no exception to the rule that obtains with all drugs.

"It should be handled carefully, administered judiciously, and under no circumstances should the public be educated in its use.

"The time has come for the profession to call a halt, and eudeavor to check the reckless use of medicines upon the part of the people.

"The secular press, in disseminating information regarding the action of drugs gleaned from medical sources, is to a large degree responsible for the drugging habits of the people; but the medical profession is not blameless in this matter, in that many physicians verbally advise the purchase of many drugs by their patients, and carelessly and thoughtlessly impress them with their harmlessness.

"9. Medicines, which are nothing more than the tools by which the physician hopes to accomplish certain ends, should no more be left in the hands of an undiscriminating lay-public to use at their pleasure, than should the equipments of a surgeon's office or the accoutrements of a standing army (all intended, if properly used, as a protection to lives of the citizens) be recklessly placed in the hands of children, or those unskilled in their use."

VOLATILE OIL OF CORIANDER.—This substance has been made the subject of experiments by M. Cadêac and M. Meunier, who have reported upon them before the *Société Nationale de Médecine*, of Lyons, at a meeting the proceedings of which are reported in *Lyon Médical*. According to these investigations, the action of coriander is more like that of fennel than like that of anise. Unlike fennel, however, it does not cause convulsions, and the authors do not feel warranted in calling it a carminative. It causes a brief stage of excitement—all the briefer as the dose is larger—followed by blunting of the sensibility, muscular relaxation and inco-ordination, and the stupor of ordinary drunkenness. Its local action is only slightly irritant, and its effects are not materially different whether it is given by the mouth, by inhalation, or by intravenous or subcutaneous injection. It is said to kill the germ of farcy in three days and that of typhoid fever in seventy hours. Meat impregnated with it becomes mummified.

—New York *Medical Journal*.

In the American *Lancet*, Dr. David Inglis, of Detroit, gives his experience in the treatment of tabes dorsalis by suspension, and concludes thus:

"As far as my own experience, as well as that of other observers goes, a genuine *cure* of tabes will be attained just as little by this as by any other plan of treatment. But, inasmuch as it is possible to obtain at least a temporary improvement of a considerable number of tormenting symptoms, no objection can be made to the treatment, if applied to proper patients and under proper restrictions.

"Suspension will probably not replace the other modes of treatment of tabes, but will afford a much desired assistance. It will not always relieve, but it enables us to alternate with the other methods for the relief and improvement of the patient's condition."

FRICTION FOR VARICES (Kobert).—

℞.—Chloride of barium . . . . . 1 gr. 5.
Distilled water, q. s.
Lanolin . . . . . 15 grammes.
Oil of sweet almonds . . . . . 5 "—

Shake mixture to dissolve the barium, and then add lanolin and oil.

M. Sig.—Rub the parts three times daily.

NATURE OF INFANTILE PNEUMONIA.—Dr. Guaita, during observations of ten years, observed 180 cases of pneumonia; of these 180 cases (in children under two years of age) 45 presented all the symptoms of croupous pneumonia.

Croupous pneumonia is, therefore, much more frequent at this early stage than has been generally admitted.

Eau De Cologne Drinking.—The use of cologne as a substitute for spirits is very common among inebriates; generally when no other form of spirits can be procured. Recently attention has been turned to the rapidly increased consumption of cologne, both in large cities of Europe and this country, and the conclusion reached by several authorities is that cologne is becoming a drink in many circles in preference to other forms of spirits.

In England many women and men in the better walks of life begin by taking a few drops of this perfume on sugar in the morning for some debility. In one instance a wineglass of cologne was taken three or four times a day for a long time; the patient finally died from delirium tremens. It appears that the effects of this drink vary but little from ordinary strong spirits, except, perhaps, there may be more profound nutrient disturbances, insomnia, and tendency to delirium. If the cologne is made from wood spirits, the brain and nerve degeneration is both intense and profound, and delirium is very sure to follow.

It has been asserted that melancholia and insomnia in a case suspected of using spirits in secret is an indication of the use of cologne. Usually the cologne drinker will have a strong odor of this perfume about his body and breath which cannot be mistaken. Such cases usually use this perfume externally in excess to divert suspicion from its internal use. Undoubtedly there are, in this country, an increasing number of cases where cologne is used secretly and exclusively. Obscure and complex nervous disorders in a woman that uses cologne externally should always suggest the possibility of its internal use. Inebriates who use it externally and recover rapidly, or make sudden changes of habits and living, may be suspected of substituting it for other spirits.—*Journal of Inebriety.*

The Geographical Distribution of Disease in Southern India.—In a leading article on this subject, Surgeon-General Bidie has taken a comprehensive view of the ravages of certain diseases in the various districts of British India, and in the course of his paper has proved that there is a marked preference for certain localities evinced by particular diseases, while also the climate of some districts seems to exert a special deleterious effect on particular organs. He also lays great stress upon the influence of the elevation of the land and the character of the subsoil upon the spread of certain diseases, especially of the miasmatic type. The cold weather, he claims, is particularly fatal to the natives, while during the dry, hot months they seem to enjoy a peculiar immunity from disease. Especially is this the case with typhoid fever, from which the natives are remarkably free.

In speaking of fevers of a malarious nature, he dwells upon the active part taken in the dissemination of the poisonous germs by the fogs which prevail at the seashore where ague is most common. The aqueous vapor enveloping the microörganisms is carried by the winds over far-reaching districts, thus bearing the germs to regions which would otherwise escape the disease.

Owing to the repugnance shown by the natives to the introduction of vaccination in the country, smallpox is generally prevalent. Of all the children born in India, probably not more tnan 16 or 17 per cent. are protected by vaccination. Phthisis also is extremely common, and is abetted in its destructive action by the debilitating influence of the famines which are so common, to which may be added the wearing effect upon the system of the national scourge, syphilis. Beri-beri is mostly to be found on the coast and in low-lying regions, where it attacks preferably the natives, although Europeans are not wholly exempt.—*British Medical Journal*, July 20.

The Curette and Paralysis of the Uterus.—Curetting the uterine cavity is an operation not unpopular with many gynecologists, and, therefore, frequently performed. It is not without danger, and requires several precautions; above all, strict precautions against sepsis. Operators have occasionally noted during the scraping process that the curette seems suddenly to go through into a space, as though it had perforated the uterine wall. Doléris has described this phenomenon, which he has found to arise from total paralysis of the uterus, due to the "minor" operation in question. Dr. Geijl, of Utrecht, confirms this theory, having observed the phenomenon in five cases. He also noted complete paralysis of the vesical walls after removal of two tumors from the bladder, and injection of boracic acid. In the case of the uterus, the curette can be passed back till it strikes against the posterior wall of the uterus, and, on introduction of the finger, the paralysed organ feels not like a flaccid bag, but rather like a distended sac. Fluids and air injected into the uterine cavity under these circumstances apparently resisted the pressure of the abdominal muscles. The question, discussed in the *Archiv für Gynäkologie*, Vol. XXXI. part 3, is of high importance, and demands further investigation.

—*British Medical Journal.*

Laxative Saline Mixture.—

℞.—Sulphate of soda,
Salt of seignette (tartrate of soda),
Cream of tartar . . . . . āā 20 grammes.
For one pint of water:
M. Sig.—One glassful before breakfast.

Tuberculosis in Some of its Surgical Aspects.—The value of excision as a method of treating tubercular joint disease is the subject of a lecture by Dr. Howard Marsh in a series upon the surgical treatment of tuberculosis. Taking into consideration the comparative results of early and late excision in a number of cases recently tabulated by eminent operators, he concludes that the statistics do not justify early operative procedures. He bases this conclusion upon the fact that systemic infection from the joints is comparatively rare, and that it is possible for the operation itself to precipitate the very result it is intended to present.—*British Medical Journal*, July 20.

Medical News and Miscellany.

Dr. Chas. Elam, of London, has just died.

An epidemic of typhoid fever is reported at Wilkesbarre.

Dr. Walling has removed to 2005 Arch Street, Philadelphia.

Dr. T. Ridgway Barker has removed to 1703 Spruce Street, Philadelphia.

Dr. Warder and family are at the Monmouth House, Spring Lake.

Dr. S. Weir Mitchell has published a volume of poems entitled "The Cup of Youth."

In France the doctor's claim on the estate of a deceased patient has precedence of all others.

An oxalic-producing ferment has been discovered by W. Zopf. He calls it saccharomyces hansenii.

There are in Japan thirty-one schools of medicine, four of pharmacy and two of veterinary surgery.

New Orleans is to have underground drainage instead of the old system of surface drainage so long in use.

M. Chevreul's successor, as professor of chemistry in the Faculty of Medicine of Paris, is Dr. Armand Gautier.

The American Rhinological Association will hold its seventh annual meeting at Chicago, Ill., October 9, 10, 11, 1889.

Dr. Joseph McFarland and Dr T. R. Keefer have been made resident physicians at the Philadelphia Hospital.

Dr. D. A. Harrison, who was elected Superintendent of the Delaware State Insane Asylum, has declined the office.

The heirs of the late M. Chevreul have presented his library of 10,000 volumes to the Paris Museum of Natural History.

The next meeting of the Mississippi Valley Medical Association will be held at Evansville, Ind., September 10, 11, 12.

The American Medical Press Association cordially welcomes its distinguished associate William Murrell, M.D., F.R.C.P., Lecturer on Pharmacology and Therapeutics in the Westminster Hospital; Examiner in Materia Medica in the University of Edinburgh, and to the Royal College of Physicians of London, etc. Dr. Murrell has just indicated his acceptance of membership, and his name has been duly entered.

Errata.—In Dr. Baruch's article entitled "The Technique of Hydrotherapeutics," August 3, line twenty-two, page 328, should read, *from a letter received by the writer from Dr. Chas. Schram.* The quotation ends after the words "in your paper, etc.," line thirty-three.

Dr. Chas. B. Nancrede, of this city, has been elected Professor of Surgery in the University of Michigan, Ann Arbor.

Sir James Paget Bart, Mr. Hutchinson, and Sir William MacCormac have been appointed members of the Standing Committee of the Father Damien Memorial Fund.

I could fill a volume with the adulterations which I have found within a few years past in articles of food and drink in common use, by microscopical and chemical analysis.—*Piper.*

Dr. Mary W. Case, of Troy, N. Y., a graduate of the Woman's Medical College of Pennsylvania, died at Lansingburgh from an accidental overdose of a drug taken for heart trouble.

After October 1, Dr. I. Minis Hays will relinquish the editorship of the *Medical News.* Dr. Hobart A. Hare, one of the editors of the *University Medical Magazine*, will assume editorial conduct.

Notwithstanding favorable reports are still sent out from the Board of Health, there is a great deal of sickness at Johnstown. The doctors are so busy that they cannot attend to calls made upon them.

The Faculty of the New York Polyclinic has been further increased by the election of Drs. H. Marion Sims and Henry C. Coe as professors of gynæcology. Dr. Coe is also appointed surgeon to the Cancer Hospital.

Dr. Emanuel Melhorn, a prominent physician of Adams County, died at his residence at New Chester. He was about sixty-five years old, and graduated at the University of Pennsylvania in 1871.

Chicago has an epidemic of typhoid fever, due to impure water. Happy is the town like Philadelphia, where the water can be cut up into blocks with a handsaw and scrubbed with a brush before it is used!
—*Press.*

Dr. Charles Theodore, Duke of Bavaria, the philanthropic physician, recently celebrated, at Tegersee, in Bavaria, his removal of the thousandth cataract from the eyes of his poor patients. It was made the occasion of a great ovation.

Seven drops of medicine which Mrs. Richards, of Turtle Creek, bought at a general store, nearly killed her infant. The medicine had been purchased from a Pittsburgh firm which had pasted paregoric labels on bottles filled with laudanum.—*Record.*

This has been a hard summer for the city poor. The Board of Health reports that, during the past four weeks, 14,995 tenements, containing 108,597 families, have been canvassed by the corps of visiting doctors, who found 5220 sick persons who had no doctor and no money to pay for one. These they cared for. Last year the total number of sick found in a term of eight weeks was 9625, and the entire number of families visitsd 211,298. The medical inspection has resulted in the abatement by the doctors of 1382 nuisances. Nearly 6000 tickets for excursions were given.—Philadelphia *Ledger.*

THE Municipal Council of Rome has decided to devote a sum of money to the formation of a Pasteur Institute. Confidence in M. Pasteur's treatment of hydrophobia is said to be increasing in Italy, as is shown by the fact that little by little all the principal towns are providing buildings for the treatment of the disease by inoculation.—*British Medical Journal.*

THE Luzerne County (Pa.) Medical Society held a lengthy session at Wilkesbarre, August 7. There was a large attendance of physicians. The matter under discustion was the typhoid fever epidemic now prevailing in that city. Dr. Woodbury, of Philadelphia, and Dr. Taylor, of the State Board of Health, were the leaders of the discussion.

THE "miraculous berry" of West Africa, the fruit of *Sideroxylon dulciferum*, was lately exhibited to the London Linnean Society. The soft, sweet pulp with which it is covered so affects the nerves of taste that sour substances—even tartaric acid, lime-juice and vinegar—have a flavor of absolute sweetness after it has been eaten. Living plants of this and of thaumatococcus, whose fruit possesses similar properties, have been received at Kew Gardens.

PROF. FRESENIUS, of Wiesbaden, after a long series of chemical analyses, declares that an egg contains as much nourishment as a pound and an ounce of cherries, a pound and a quarter of grapes, a pound and a half of russet apples, two pounds of gooseberries or four pounds of pears, and that 114 pounds of grapes, 127 pounds of russet apples, 192 pounds of pears and 327 pounds of plums are equal in nourishment to 100 pounds of potatoes.

THROUGH the liberality of Lady Kortright, who has so bountifully endowed the Presbyterian Hospital in this city, another institution will shortly come into existence and serve as a monument to her munificence.

The property contains 49¾ acres, and the price was $30,000. The home will practically be an annex to the Presbyterian Hospital, and when completed will pass into the control of the Trustees of that institution.

The location is very picturesque. Its view reaches the Blue Mountain range, and it has superior attraction in the way of trees and water. It is only a half mile from Devon Station, and a Telford road reaches almost to it.

THE Cincinnati doctors have decided that the man Steel has blood poison. He will sue for $5000 damages. Filden Weir, the first man experimented on here, whose wonderful cure was telegraphed broadcast, is in bed again. He, too, will sue. Great hard lumps appear where the incisions were made, and he is delirious.

Dr. Longfellow, who made the first experiment, in a published statement, says he has lost faith in the elixir, and that a local paper paid all the expenses of his experiments for first news.

Dr. Langenbeck, the chemist who prepared nine-tenths of all the elixir used, says it is dangerous if used after an hour, and a rank poison after ten hours. The scare amounts to a craze.—*Press.*

DR. JACKSON, of Pittsburgh, who is experimenting with Brown-Séquard's elixir of life, reports that a bald-headed old gentleman whom he injected returned saying he could almost feel the hair starting on top of his head.

G. S. SYMONS, an eminent English meteorologist, has argued in a recent scientific paper, that people in a thunder shower should allow themselves to become thoroughly drenched with the rain, as then it would be impossible for the lightning to kill them.

IN prescribing acetanilide for children, Dr. I. N. Love recommends the following formula:

℞.—Acetanilide (Lehn & Fink)	. . . .	gr. xxx.
Alcohol	. . . . .	dram. iij.
Glycerin	. . . . .	" ij.
Aquæ cinnamon	. . . . .	" iij.
Syr. tolu	. . . . .	oz. j.

℥. One to three teaspoonfuls every two or three hours.

THE Astley-Cooper prize, amounting to $1500, will be awarded in 1892. The question proposed is, The Influence of Microörganisms upon Inflammation. The papers must be written in English, or accompanied by an English translation, and should be addressed before January 1, 1802, to Guy's Hospital, London. The prize will not be awarded to two or three working conjointly.

OWING to a reduction in the appropriations, three of the national quarantine stations on the Atlantic coast, one in the Gulf, and two on the Pacific coast, will be closed on October 1. The governmental appropriation amounts to $50,000, and as this amount is insufficient to maintain all the stations now in operation throughout the year, two only will be kept open, namely, the one at San Francisco and one on the Gulf coast.—*Sanitary News.*

MUMMIFICATION OF THE UMBILICAL CORD.—In the *Liverpool Medico-Chirurgical Journal* for July, 1889, there is an account of an interesting case of the above-mentioned condition by Mr. Frederick W. Towndes, Surgeon to the Liverpool police. At the end of 1885 the body of a fully developed, newly born male child was found in a cellar, with a scarf tied tightly round the neck. The lungs gave evidence that the child had respired. The point of chief importance, however, pertains to the state of the umbilical cord. "For about half an inch from the navel it was perfectly fresh; then came the usual line of demarcation; the remainder of the cord, about two inches and a half, was completely mummified, and there were no appearances of any ligature." We are quite in accord with the opinion of Mr. Lowndes that the state of the cord showed indisputably that the child had survived its birth for "at least twenty-four hours," since the change which had taken place was a vital one, and not the result of mere post-mortem desiccation. We are indebted to Mr. Lowndes for putting this practically unique case on record, if only for the fact that it shows that Casper's deductions from his observations on the value of mummification of the umbilical cord as a means of determining live birth are too general.—*The Lancet.*

THOMAS D. WESTCOTT, M.D., a son of the late Ebenezer Westcott, who was a well-known railroad man, died at his residence in Camden, N. J. The deceased was born at Tuckahoe, Cape May County, in 1838. He was educated at the University at Lewisburg, Pa., and graduated from the Jefferson Medical College. He practised medicine for a number of years at Port Elizabeth, Fairton, and also in Camden. He relinquished the practice of medicine about fifteen years ago.—*Ledger.*

A ROYAL OPHTHALMOLOGIST.—H. R. H. Duke Charles, M.D., of Bavaria, continues in the Bavarian Tyrol the philanthropic practice of ophthalmic surgery, to which he devotes the spring months in the Austrian Tyrol. On the 3d instant, at the Tegern See, he performed with complete success his one-thousandth operation for cataract. For the occasion, which was a festive one, the surgical theatre was decorated with flowers by the sisters of the hospital, of which his Royal Highness is the patron and working president.—*Lancet*, July 13, 1889.

IN regard to medical practice in France the editor of the *British Medical Journal* says:

"Many of the evils which we deplore do not exist in France. The chemist does not compete with the doctor, and the prescribing pharmacist is pursu d with the utmost rigor of the law; the sick club is much less developed, the out-patient department is barely a disturbing element; there is only one degree, which requires a preliminary degree in arts, and five to six years' study; the sham dispensary does not exist; yet the struggle for existence is deplorably severe.

OUR elaborate code of by-laws for the suppression of holiday recreations can still be circumvented by the resources of opulence, and the well-known hopelessness of any other expedient has stimulated a race for wealth which does not hesitate to attain its object at any risk of social or sanitary consequences. The number of infants which the superstition of the Ammonites sacrificed to Moloch is a mere trifle compared with the multitude of children now devoted to a far more cruel fate by being literally drudged to death in crowded factories to enable a millionaire to save a few dimes on his weekly pay roll and add a few per cent. to the exorbitant rate of his yearly profits.

In times of general scarcity the market has been drained of its scant supplies by speculators trying to coin gain from the distress of their fellow men and risking, after all, to be foiled by the decay of their hoarded stores or their destruction by fire or flood. Quack nostrums, which not one intelligent man in a hundred would privately hesitate to pronounce infinitely worse than worthless, are sold by shiploads and carloads to disseminate disease and the seeds of the stimulant vice, and the saints who contribute thousands to insure the theological soundness of the Quaggalla Hottentots do not care enough for the physical health of their countrymen to whisper a word against the lawfulness of the infamous traffic.

Popular Science Monthly.

THE "Woman's Cat"—*La Femme-chat*—who has just escaped from the Saltpetriere Hospital, forms a frequent topic of sensational talk and conjecture just now. It appears that last week a good-looking and apparently healthy girl of fifteen was taken to the hospital by her friends. She was examined by Dr. Parinaud, and while he was looking at her eyes she suddenly went on all fours, her features becoming distorted, her eyes glared, and, imitating the mewing of a cat, she endeavored to bite the persons who were standing near her. After having acted for several moments in this manner the patient began to lick her hands, and then gradually returned to her senses. When under examination by Dr. Charcot the girl had another attack of her malady, which is called *galeanthropie hysterique*, and she bit the eminent surgeon severely in the leg. Dr. Charcot had hopes of curing the patient, but she has suddenly disappeared from the Saltpetriere, and is now wandering at large through Paris.—*Paris Letter in London News.*

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 13, 1889, to August 19, 1889.

HEGER, ANTHONY, Lieutenant-Colonel and Surgeon; SKINNER, JOHN O., Captain and Assistant-Surgeon; MORRILL, JAMES C., Captain and Assistant-Surgeon. Will assemble, by direction of the Secretary of War, as a board of medical officers, at the U. S. Military Academy, West Point, N. Y., on August 25, 1889, or as soon thereafter as practicable, to examine into the physical qualifications of the candidates for admission to the Academy. Par. 9, S. O. 185, A. G. O., August 12, 1889.

GARDNER, WILLIAM H., Major and Surgeon (Washington Barracks). Is hereby granted leave of absence for one month. Par. 1, S. O. 183, Headquarters Division of the Atlantic, Governor's Island, N. Y. City, August 13, 1889.

MATTHEWS, WASHINGTON, Major and Surgeon. Is promoted to Surgeon, with rank of Major, to take effect from the tenth day of July, 1889, *vice* Tonn, promoted. War Department, Washington, D. C., August 14, 1889.

HAVARD, VALERY, Captain and Assistant-Surgeon. Is granted leave of absence for one month, to take effect about October 5, 1889, with permission to apply to Division Headquarters for an extension of one month. Par. 3, S. O. 68, Department Dakota, St. Paul, August 10, 1889.

PORTER, JOSEPH Y., Captain and Assistant-Surgeon (now at Jacksonville, Fla.). Will, if the state of his health will permit, by direction of the Secretary of War, proceed to Jackson Barracks, La., and report to the commanding officer of that post for temporary duty, and by letter to the commanding general, Division of the Atlantic. Par. 16, S. O. 186, A. G. O., August 13, 1889.

Changes in the Medical Corps of the United States Navy for the week ending August 17, 1889.

ROGERS, B. F., Surgeon. Detached from U. S. S. "Alliance," and wait orders.

HARRISON, G. E. H., Surgeon. Ordered to the U. S. S. "Constellation," August 13.

LOWNDES, C. H. T., Assistant-Surgeon. Ordered to the U. S. S. "Constellation," August 13.

DECKER, C. J., Assistant-Surgeon. Detached from U. S. S. "Lancaster," and granted four months' leave of absence.

BALDWIN, L. B., Passed Assistant-Surgeon. Detached from U. S. S. "Ranger," ordered home and wait orders.

HARVEY, H. P. Surgeon. Ordered to the U. S. S. "Ranger."

LOVERING, P. A., Passed Assistant-Surgeon. Ordered to the Receiving-ship "Wabash" at Boston Navy Yard.

SIEGFRIED, C. A., Surgeon. Ordered to the Naval Station at New London, Conn.

Medical Index.

We purpose in this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Associated dining rooms and employment of the insane, the moral and curative effects of, Preston. Virginia Medical Monthly, August, 1889.

Acetanilide in pediatric practice, one year of, Love. N. E. Med. Monthly, August 15, 1889.

Aneurism of the ascending aorta, clinical lecture on, Comingor. Virginia Med. Monthly, August, 1889.

Apostoli's method, with reports of cases, a year's experience with, Smith. Amer. Jour. of Obstetrics, August, 1889.

Address, the president's, before the American Medical Association, Douson. N. E. Med. Monthly, August 15, 1889.

Consumption among the Sioux Indians, Treon. Cincinnati Lancet-Clinic, August 10, 1889.

Cocaine in eye, ear and throat practice, Dobney. American Practitioner and News, August 3, 1889.

Creasote, a practical study of, Atkinson. Maryland Med. Jour., August 10, 1889.

Chirurgische aphorismen, Lange. Medicinische Monatschrift, August, 1889.

Diphtherie traités par la méthode du Dr. Gaucher, au sujet de plusieurs cas de, Crésantignes. La France Médicale, Samedi, 3 Août, 1889.

Diphtheritic membrane, a solvent for, Wile. N. E. Med. Monthly, August 15, 1889.

Ectopic pregnancy and pelvic hematocele, Wathen. Amer. Jour. of Obstetrics, August, 1889.

Extra uterine pregnancy, Thompson. *Ibid.*

Gangrene gazeuse foudroyante, Montgomery. Pacific Med. Jour., August, 1889.

Gaseous gangrene, Sherman. *Ibid.*

Hydrocephalic monster with cerebellum enormously developed outside the cranial cavity, Leonard. Amer. Jour. of Obstetrics, August, 1889.

Heart disease, a new diuretic for, Germain Sée. The Medical Age, August 10, 1889.

Intestinal diseases of children during hot weather, Hooper. *Ibid.*

Infant feeding, the problem of, Love. N. E. Med. Monthly, August 15, 1889.

Inebriety, distinctive forms of, Wright. Virginia Med. Monthly, August, 1889.

Insanity and allied affections, Hodgdon. Maryland Med. Jour., August 10, 1889.

Malpractice suits, Ellinwood. Pacific Med. Jour., August, 1889.

Metrorrhagia, report of a case of, Stapleford. Cincinnati Lancet-Clinic, August 10, 1889.

Manchester murder, homicidal chloral poisoning with its medico-legal relations, Reynolds. British Med. Jour., August 3, 1889.

Obstetrics, a peculiar case of, Brown. Pacific Med. Jour., August, 1889.

Old bilateral dislocation of the elbow, Ronsohoff. Cincinnati Lancet-Clinic, August 10, 1889.

Priapism, a case of, of several years, Ducatur. Pacific Med. Jour., August, 1889.

Presidential address on the history and work of a cottage hospital during twenty years, Holden. British Med. Jour., August 3, 1889.

Paroxysmal, congestive, hepatic, hæmaturia, Gary. Virginia Med. Monthly, August, 1889.

Suspension for paralysis, Kellogg. Pacific Med. Jour., August, 1889.

Selenic acid and other selenium compounds, researches in the chemistry of, Cameron and Macollon. Dublin Jour. of Med. Science, August, 1889.

Spina-bifida with spinal meningocele delaying delivery, De Forrest. N. E. Med. Monthly, August 15, 1889.

Sanitary Science, aids to. Hospital Gazette, August 10, 1889.

Structure of the vertebrate liver, report on the (abstract), Shore and Jones. British Med. Jour, August 3, 1889.

Surgery of the abdomen, a contribution to the, McArdle. Dublin Jour. of Med. Science, August, 1889.

Therapie der hysterie und neurasthenie, Laufenauer. Int-klin. Rundschau, Vienna, July 21, 1889.

Two ovariotomies, Smith. Pacific Med. Jour., August, 1889.

Transfusion, summary of three lectures on, Hunter. British Med. Jour., August 3, 1889.

Clinical Lecture.

A LECTURE ON VARICOCELE.

(Delivered at the College of Physicians and Surgeons, Chicago, Ill.

BY G. FRANK LYDSTON, M.D.,
CHICAGO, ILL.

PART I.

GENTLEMEN: Varicocele is one of the most frequent affections of the male genito-urinary apparatus. Fortunately, however, it is not intrinsically a serious disease, and is in by far the majority of cases tolerated indefinitely, producing, as a rule, comparatively little discomfort. In a certain proportion of cases, however, the disease becomes sufficiently pronounced to induce the patient to consult the surgeon, and to justify the use of support or even the adoption of surgical procedures of an operative character for its relief.

The disease consists in a dilatation of, with accompanying changes in, the walls of the veins of the plexus surrounding the spermatic cord. In a general way, these changes resemble those which occur in varix in other situations, the causes being essentially the same if we exclude the influence of masturbation and sexual excesses. Varicocele occurs in quite a large proportion of adult males, the proportion, according to some authorities, being as high as one in ten. Landouzy,[1] an old French writer, stated that it occurred in 60 per cent. of adult males. This, however, is undoubtedly an exaggeration, unless we accept as cases of varicocele the slighter forms of dilatation of the spermatic veins.

Henry,[2] however, found but forty-one varicoceles in nearly two thousand examinations as police surgeon, but this observation is not an accurate criterion of the frequency of the disease, for the applicants for positions upon the New York Police Force are certainly exceptional from a physical standpoint, and, on the average, less likely to have varicocele than almost any other class of men that could be mentioned.

The frequency of varicocele diminishes markedly with increasing age. M. Horteloup,[3] Surgeon to the Bicêtre, found 42 subjects with varicocele among 1600 individuals, and of these but 16 were above twenty-five years of age; of the total number of varicoceles, 14 increased as the patients grew older, 19 remained stationary, 8 diminished, and 1 entirely disappeared.

Varicocele is much more frequent than varices in other situations, this being due to the fact that there exists, in addition to the general causes of venous dilatation, certain special causes due to anatomical peculiarities of the affected structure. The veins which return the blood from the testicle are of considerable size, and follow a winding course as they leave that organ and ascend upon the spermatic cord. They are arranged in a peculiar manner, constituting a plexus surrounding the cord (pampiniform plexus),

[1] Du varicocèle et en particulier de la cure radicale de cette affection.

[2] *Medical Record*, New York, 1882.

[3] Memoire à l'Acad., inedit.

the vessels which anastomose at frequent intervals. The valves of the veins constituting this plexus are very defective, and it is possible to inject fluid from above downwards past the valves with very little pressure. As compared with the veins in other portions of the body, those of the pampiniform or spermatic plexus are illy supported by the connective tissue about them, it being in this situation loose, sparse, and inelastic. The spermatic veins are very long, and even if their valves were not defective there would be a tendency to dilatation on account of the insufficient support to their walls afforded by the cellular tissue, and the great weight of the long column of blood which must necessarily rise perpendicularly in order to empty itself into the large venous channels of the abdomen. Pressure upon the veins as they traverse the inguinal canal is an important factor in the production of varicocele, and is due to straining efforts of various kinds, and particularly those involved in defecation, if the bowels be constipated. The left spermatic plexus is generally affected in preference to the right. The reasons that have been advanced in explanation of this fact are: 1. The lower position of the left testicle. 2. The relative acuteness of the angle formed by the junction of the left spermatic vein with the renal. 3. The close proximity of the left spermatic vein to the sigmoid flexure of the colon and its consequent exposure to pressure in constipation. 4. The absence of a valve in the left spermatic vein at its junction with the renal vein. 5. Tendency on the part of men to stand upon the left foot.

It would seem that the relatively greater weight of the column of blood in the left spermatic plexus, due to the fact that the cord and its accompanying veins are longer than upon the right side, is a sufficient explanation for the preponderance of varicocele upon the left side.

The causes of varices in general are several. It is probable that an inherent lack of tone of the venous walls is the foundation of the majority of cases of the disease. This is usually designated as hereditary or congenital predisposition. Individuals who are debilitated from any cause are most liable to the occurrence of varicose veins. In such conditions the walls of the veins are lax, flabby, and unresisting, and inasmuch as the same causes which produce this condition of affairs also weaken the heart's action, there is a deficiency in the *vis a tergo*, which constitutes an important element in the propulsion of the blood through the veins, as well as a deficiency in the aspirating power of the heart and lungs within the chest. These same patients present a tendency to hemorrhages, on account of a lack of vascular tone, and I have noticed that in a general way the existence of varices in patients about to be operated upon is a note of warning as regards possible serious hemorrhage. Persons who suffer from such diseases as purpura and scurvy are particularly liable to relaxed and dilated conditions of the veins. Strumous individuals also present a tendency to varices. Persons of indolent habits are quite apt to have varices, because of a defective circulation, as well as the relaxed condition of the vascular walls produced by the general lack of tone incidental to insufficient exercise. Such subjects who are compelled to stand at their work for prolonged periods are peculiarly subject to varicose veins. Certain diseases of the heart, liver, lungs, and peritoneal cavity, which induce by pressure obstruction to the return flow of blood through the vena cava and iliac veins, favor the occurrence of varix. In cases of obstruction to the portal circulation of long standing, varicocele is liable to occur in conjunction with hemorrhoids.

Masturbation, sexual excess, and prolonged venereal excitement without gratification are undoubtedly responsible for varicocele in some instances. It is improbable that these causes, if brought to play for the first time in a healthy adult, would produce much effect, but occurring as they do when tissue development is really in excess as compared with the inherent resisting power or strength of the various bodily structures, they operate very powerfully in producing congestion, and finally dilatation of the spermatic plexus. It will be found, however, that in a large proportion of cases which seem to be directly attributable to these causes, there exists a foundation for the disease in the form of an inherent defective tone of the vascular walls, akin, perhaps, to that mysterious condition which exists in hæmatophilia as far as its hereditary character is concerned. Inasmuch as it is an established fact that the disease alluded to is of an hereditary nature, and is to a certain extent dependent upon defective arterial contractility, it is logical to infer that a similarly defective tone of the venous walls may exist, and be of a similarly hereditary character.

When associated with other causes of varicocele, chronic constipation has an important influence in its production; obviously the pressure of the accumulated fæces upon the spermatic vein produces more or less obstruction to the return circulation. The pressure of a truss occasionally induces varicocele in conjunction with hernia. The disease has been known to occur as a consequence of lifting or athletic strain of various kinds. I have seen several cases of this sort. Dr. Keyes also describes this form of the disease. Percival Pott reported several cases of "acute varicocele" due to a combination of fatigue, injury to the part, and exposure to cold, the condition being followed by complete atrophy of the testicle. These cases were undoubtedly phlebitis of the spermatic veins, which condition gave rise to a proliferation of connective tissue that permanently occluded their lumen.

Varicocele occurs with the greatest frequency between the ages of fifteen and thirty-five,[1] this being the period when all the faculties of the body are at their maximum and physical growth is the most active. It is also at this period that perverted sexual habits and hygiene are apt to enter into the daily life of the patient, either in the form of sexual excess, sexual excitement without gratification, or masturbation.

The anatomical changes in varicocele involve chiefly a dilatation and tortuosity of the veins with a loss of

[1] M. Edmond Wickham, "Laresection du scrotum," 1885.

elasticity and contractility. There is usually more or less increase in the thickness of the venous walls. This, however, does not make them proportionately stronger, because of the fact that the vessel is enormously dilated, and consequently its walls are thinner in proportion to the weight of its contents than is the case with the normal vessels. It would seem that the elastic and contractile tissue of the venous walls is absorbed in varicocele, and replaced by a low grade of connective or fibro-connective tissue. Chronic inflammation (*chronic phlebitis*) may occur and enhance the vascular thickening. In some instances concretions (*phleboliths*) are found within the veins and may be felt from the exterior. The valves of the veins are almost completely destroyed as far as their functionating capacity is concerned, and in different portions of the venous walls spots of fatty degeneration may exist. The scrotum is always thin and relaxed, its muscular tissue being greatly weakened, and as an evidence of the general character of the affection and its dependence upon an inherent lack of vascular tone, the scrotal veins are often enormously dilated and tortuous.

The symptoms of varicocele vary with the severity of the affection. The first thing which attracts the attention of the patient is usually enlargement of the veins, producing a slightly tumorous condition of—as the patient supposes—the testicle. This enlargement in the majority of cases is so slight as to be of no practical importance, its principal effect being a resulting disturbance of the morale of the patient. These individuals who consult the surgeon regarding the slighter forms of varicocele are generally masturbators, who have become aware of the evil effects of the habit, and under the stimulation of quack literature are practising a most rigorous introspection and frantically searching for morbid effects of their vicious habits. In their daily inspection of their genitalia they accidentally discover a slight enlargement of one or the other testicle with an attendant relaxation of the scrotum.

Possibly their attention is at this time first called to the fact that one testicle hangs lower than the other. The discovery of these things in combination with their apprehensions alarms the patient and induces him to seek relief, but too often impels him to consult the quack, who finds in such victims his most profitable patients, particularly if spermatorrhœa or nocturnal emissions coexist, as is quite apt to be the case. These slight enlargements of the spermatic veins are due to imperfect sexual hygiene with attendant vascular congestion; they generally disappear after normal sexual relations have been established, and it is very rarely that the practitioner is again consulted when such patients are happily married. Operative interference in these cases is unwarrantable, and in the opinion of conscientious surgeons is dishonest.

Varicocele in its more marked forms is very readily recognized. It presents a soft, mushy tumor, which has been said to impart to the fingers a sensation as of a bundle of worms within a sac, this being as accurate as any description which could be given. The veins of the scrotum are often tortuous and dilated. The tumor is not tender upon pressure unless phlebitis exists. Phleboliths are sometimes to be detected within the cavity of the veins.

The *subjective symptoms* are both mental and physical in character. In nearly all well-marked cases the disease gives rise to considerable mental annoyance as well as a varied degree of actual physical suffering. In nearly every young man, who is affected with a varicocele sufficiently marked to attract his attention, a greater or less degree of mental depression and sexual hypochondriasis exist, and, indeed, in certain instances, serve to make life miserable. If the patient be at all sensitive, the physical deformity which the varix occasions may give rise to great annoyance. There is unquestionably in all cases of pronounced varicocele a marked lack of tone of the sexual apparatus; pseudo-impotency, frequent polutions, and spermatorrhœa are often conjoined with varicocele, and may persist after that condition has been operated upon. Irritability of the neck of the bladder, neuralgia of the testes, dragging pains along the spermatic cord, pain in the back and thighs are among the more disagreeable symptoms produced by the disease. When the scrotum is extremely lax and pendulous, its veins being dilated and tortuous, it may give rise to considerable mechanical discomfort. Should the sudoriferous secretion of the relaxed scrotum be excessive, pruritis with perhaps eczema of the scrotum may exist.

The pain and mental discomfort incidental to varicocele is not necessarily proportionate to the severity of the disease. Some cases with a very slight varicocele are profoundly depressed and complain greatly of reflex neuralgic pains in the back, thighs, and testes, with associated pronounced mental depression. In other cases a very large varicocele may produce no discomfort whatever, save that which is incidental to its size and consequent mechanical effects, locomotion being in some cases somewhat impeded.

The symptoms incidental to varicocele have been observed to improve temporarily after sexual intercourse.[1]

[To be continued.]

THE CLINICAL USES OF ELECTRICITY.

By JOHN V. SHOEMAKER, A.M., M.D.,
PHILADELPHIA, PA.

THE employment of electricity as a therapeutic agent has been subject to undulations of hope and unbelief for many years past. No remedy of equal value has been so misused; so much exaggerated as to intrinsic worth; or so greatly decried as worthless; and this by those who from education, opportunity and position should have weighed their opinions carefully before sending them forth to influence for good or evil the efforts of less able practitioners in their work amongst the sick. The mechanism for operating electric force has improved much more rapidly than the intelligent use of it in the past ten years. We now possess efficient galvanic

[1] Landouzy, op. cit.

apparatus for any purpose; good faradic and static machines for utilizing currents of high tension; the dynamo is so well understood as to be a good instrument for practical use; whilst the secondary accumulator is so near perfection as to make electric storage possible, and by it we may carry from place to place the hidden energy which dispels the malady or illumines the recesses of the body hitherto shrouded in darkness. No department of therapeutics exists in which electricity is not useful, but we at present note only a few of the more prominent affections in which undoubted success follows its intelligent use, and disorders of the nervous system will receive the first notice. To begin with, the diagnosis of nervous disease is greatly facilitated by electric investigation. A paralysis may be local or central, and at times ordinary tests render the detection of its cause difficult. For instance, a man who, in ordinarily good health, gradually loses the power of using his arm on one side until he at last is compelled to stop his usual work. A blow on the shoulder long ago would suggest nerve injury, yet the muscular development is good. Now, under both galvanism and faradism the electrical reactions are normal, not only throughout the sound part of the body, but in the paralyzed arm also, despite the chronic nature of his disease, hence we may infer the lesion to be cephalic, not spinal, and subsequent post-mortem examination confirmed the opinion. Again, a man suffers from similar symptoms as the one above noted, but the progress is more rapid and some atrophy of muscle is apparent, at first in one arm, after some weeks in both. Reaction to the current was normal when locally applied, hence peripheral lesion was absent and the atrophy becoming definite on each side we concluded the disorder to be spinal. This was also verified by an autopsy. After a fall a man at once finds one arm to be painful, he suspects neuralgia and treats it with home-made lotions. Soon weakness of the limb supervenes with numbness of one or more fingers. No muscular atrophy, but pain at all points over the ulnar nerve. Some muscles and nerves only respond on the injured side to currents and all do on the other. The lesion was then declared to be peripheral, and prompt recovery proved this to be true. In neuralgias, so common, we may often determine whether the pain is a pure neuralgia or a hysterical or pseudo-neuralgia, because the first yields to galvanism whilst the second is benefited by faradism only. So much for diagnosis. In the treatment of nervous disorders neuralgia claims attention prominently because it is so amenable to the constant current. In a case of severe cervico-brachial pain, of intermittent character, which compelled a lady to resign her position as clerk, and in which the numerous antiperiodics and tonics with narcotics failed, galvanism applied, the positive (stabile) to the shoulder and the negative to the arm, forearm and hand (labile), with a current beginning at 5 ma. and running up to 60 ma. daily, cured her in three weeks. She had been sick for four years previously, but now remains well after three years.

Another instance was that of a washerwoman who suffered from a severe facial pain, involving the cheek, eye and temple of one side. She had had nausea, constipation, and no appetite. For these symptoms the patient was treated for liver and stomach disorder by one physician, by another for kidney disease, and for dyspepsia by still another. Next, a gynecologist treated her womb and ovaries, but all to no purpose. Pressure over the focal points caused relief more than pain, hence faradism was used, a moderate current traversing the sensative parts on the face and passing to the nape of the neck removed all the symptoms in some twenty-five applications. A combination or alternation of general faradization and localized galvanization along the spine is wonderfully efficacious in all forms of hysteria and spinal irritability. Many nervous girls, who are a burden to themselves and their families, are brought into a new enjoyment of life by this manner of therapeusis. More attention to careful electro-therapeutics and less to uterine suspicions would save many innocent appendages and remove discreditable abdominal surgery to a large extent in the domain of female hysteria. Epilepsy and epileptiform seizures are at times susceptible of cure or material benefit by galvanism. The preferable method is to apply descending currents from the vertex to the epigastrium. If convenient the current should be applied so as to anticipate the spasm, and experience has shown its power to cut the seizure short, as to duration, or sometimes abort it, The bromides are heightened in their effect by conjoined electrization, and when minor epilepsy is simply held in check by bromine, electricity should at least receive a fair trial, because in the hands of experts it has completed a cure in many such cases. Chorea and allied tremor is often notably relieved by general galvanization. Cases occur in which a single muscle will twitch, as, for instance, that one short in extent but long in name, the levator labii superioris et alaeque nasi. Local faradization has often cured such spasm, as also that of one or both eyelids. The ordinary chorea of schools is usually cut short by strong faradism of the entire surface. The various paralyses afford a wide field for electrical treatment, of course, when dependent on central lesion, such as pressure from intercranial hemorrhage, time should be given for thorough absorption of the clot, but in from six to twelve weeks after the onset no remedy equals faradization locally to the affected muscles. Gentle galvanization of the brain shortly after the seizure undoubtedly tends to hasten absorption of the effusion. In Bell's palsy nothing exceeds in usefulness localized galvanism. The affected muscles should be picked out separately and submitted to treatment one at a time. At times when the constant current is tardy in acting, static sparks may be advantageously substituted. Recovery is so quickly attained in some cases as to astonish the patient, who, if a lady, is naturally solicitous about the distortion which is annoying to her. Galvanism is of value in some diseases of the eye; Dr. C. S. Bull, in the New York *Medical Journal*, April 27, reports that, "In traumatic anæsthesia of the optic nerve and retina, uncomplicated by any laceration of nerve tissue or rupture of nerve fibers, galvanism carefully and per-

sistently applied has been known to produce a rapid and permanent improvement of vision, when applied directly to the closed lids, and the current passed through the eyeball."

The knife pains of locomotor ataxia are susceptible of amelioration under galvanism and spinal galvanization has, in several marked instances, so greatly improved the patient as to permit his going about after treatment, when before it he had been confined to his chair or couch. Sciatica may always be relieved during the acute paroxysms by galvanism applied by descending currents, and permanent cures have been frequently attained by electro-puncture, the needle being thrust down to the nerve at one or more points along the painful portion of it. Neurasthenia whilst not always cured by electricity alone, although it frequently is, may be overcome by combined electro-massage, and this without the gorging which has characterized the treatment of this apparently universal complaint, and which has done much more harm than good to the patient. In this affection a combined general galvanization and faradization are indicated daily. Many eminent alienists, particularly abroad, are reporting favorably on the use of galvanism in mental disorders. Melancholia, with or without delusion, is apparently benefited by prolonged treatment and without commitment to an asylum. In Philadelphia a professional friend has secured extremely good results in some very decided and obstinate instances which have not yet been reported, although he will shortly detail them. Others presenting delusional or mono-maniac features, which had resisted routine asylum treatment, were thoroughly restored under cerebro-spinal galvanization. In uterine disorders electricity is indispensable. Authentic extra-uterine pregnancies have been cut short by either current. Some operators prefering one, some the other. In dysmenorrhœa, intra-uterine galvanism carried to high power is of great service, whilst in amenorrhœa under faradism, through the ovaries and uterus, the flow is shortly established. Menorrhagia arising from relaxed uterine walls is specially benefited by faradism, and when dependent on villous growth of the endothelium, the use of cauterant galvanic currents will remove the cause. In disorders of the intestinal canal we derive special benefit from electrical treatment. The ceaseless drugging may be avoided in that prevalent trouble, constipation, by methodical faradization. No remedy will more promptly or more certainly tone up the intestinal muscular fiber than electricity, or cause it to contract more promptly. General faradization of the abdomen every morning will always succeed in provoking a movement of the bowels. Moreover, the result is not only prompt, but it is permanent. The protean forms of dyspepsia are amenable to electrical treatment. Indigestion from defective secretion of the gastric fluid is overcome by local galvanism. Glandular action is stimulated and the muscular tone also of the stomach is enhanced under the same method. Gastralgia and stomach cramp are usually relieved at once by galvanism, as is pyrosis and the vomiting of pregnancy. Mild currents of not beyond 15 ma. are needed. The anode may be placed upon the cervical spine and the cathode over the epigastrium. Torpor of the liver is readily overcome by the use of strong faradic currents, or if chosen, static insolation and drawing of sparks is a proper substitute. Several instances of dislodgment of impacted gallstones have been reported by well-known electrologists, and as we have no special remedy for this painful and distressing malady, except *dioscorea villosa*, electricity should always be given a trial. Hemorrhoids or piles, although not precisely a disease of the digestive tract, so often depend on blocking of the chylo-poietic circulation as to admit notice at this time. The aching attendant on congested piles is dispelled in many instances by placing the anode on the anus, the cathode over the liver, and passing from 20 to 30 ma, for fifteen minutes. So much is being said at present concerning high electrolytic currents in uterine myoma as to render reference to the matter hardly necessary beyond stating that despite the evident success of the method many surgeons decry the procedure, not because personal experience prompts their utterance (for those who rail most loudly against electrolysis are the ones who are ignorant of electro-therapeutics), but because the new method supplants, in suitable cases, the use of the knife. In connection with the use of electricity in gynæcological practice, we note the article from the pen of Dr. Goelet, of New York, in the New York *Medical Journal* for June 8, 1889, advocating the use of electricity instead of laparotomy in diseases of the uterine appendages. The paper is a timely one, and if it will stay the indiscriminate operations of abdominal surgeons, or if it attracts the attention which it deserves, it will act as a needed missionary. Dr. W. R. D. Blackwood, of Philadelphia, has advocated electrotherapy in gynecology for fifteen years past before the Philadelphia County Medical Society, and defended it against the adverse comments of leading obstetricians in that body, and in many papers in the *Medical and Surgical Reporter*, the Philadelphia *Medical Times*, the *Medical Bulletin*, and THE MEDICAL REGISTER of this city; with a paper in the New York *Journal of Obstetrics* many years ago. The employment of currents far beyond those used at the times indicated was insisted on by Dr. Blackwood, in spite of the condemnation of his auditors, particularly in the Society named.

We may say, however, that the doctor, whilst endorsing the views of Dr. Goelet, stated to the writer that he objected to the plaster-of-Paris coating on the electrodes as being a non-conductor, he preferring simple cotton thoroughly wet with any suitable antiseptic solution. The electrodes used by Dr. Goelet are similar to those illustrated by Dr. Blackwood in his papers. (See The Electrical Treatment of Dysmenorrhœa, Philadelphia *Medical Times*, October 9, 1880.)

The great difficulty in managing diseases of the uterus and its appendages by electricity is the want of skill on the part of the operator, and the employment of inadequate apparatus. Time will not at present permit fuller allusion to this matter, but it is of vital importance to thinking men who have the

real good of their patients at heart, and the admissions of gynæcologists, who, after years of laparotomizing, now confess that a large percentage of their operations fail to relieve their patients.

In urethral stricture of the male an advance has been made which incontestably proves the value of electrolysis in that common and troublesome affection. Hundreds of cases have already been successfully treated in our large cities, particularly under Newman, of New York. Contracture of any duct, such as the lachrymal canal, the œsophagus, or the Eustachian tube, is amenable to electrolytic method, although the field as yet is not very extended. Prostatorrhœa and enlarged prostate receive benefit from galvanism applied by a suitable bougie and intra-rectal rheophore.

In extreme hypertrophy of the gland the negative may be applied by a well-insulated needle introduced per anum, and as high a current as can be borne (say 75 to 150 ma.), should be used for from three to five minutes, about three days elapsing between each treatment. The indifferent electrode may be applied over the abdomen or on the thigh. A modification in the application of strong currents brings into use the electric cautery. In it we possess great advantage over the écrasure, or similar instruments for the removal of growths by electricity, for the galvanic loop is rapid yet bloodless, and intrinsically aseptic in its operation. Before leaving electrolysis, it may be well to allude to principles governing the use or choice of the active electrode in definite instances. When a current capable of disintegrating substances is used the various salts of the tissues are found at the negative pole, the lime soda and potassa. The acids and oxygen go to the positive. Of course, chemical local action is set up around the poles in contact with the electrodes, hence care must be used that we select the proper pole according to what we desire to do. In electrolysis of a fibroid we aim at disintegration, hence the negative is introduced by needles into the mass. The result is a liquefaction of the part caused by the electro-chemical caustic action, and its extent is governed by the strength of current. If on the contrary, we propose arresting hemorrhage from a bleeding myoma we depend on positive polar action, because the tendency of that pole is to coagulate blood or to seal up patulous capillaries, if they are not too large. It would, therefore, be a serious blunder to employ either pole indiscriminately in electrolysis of urethral stricture, or in the treatment of uterine fibroids. Great harm has already been done through ignorance of the fundamental principles here alluded to. The use of electricity in pulmonary disorders has not received the attention which it deserves. In the service of Dr. W. R. D. Blackwood, at St. Mary's Hospital, of Philadelphia, very decided relief has ensued in cases of phthisis under the application of both faradic and static treatment. The debilitating night sweats were often checked for a week after the first dose, and the chest pains were considerably diminished. The nutrition was sometime greatly heightened, and this gain alone was valuable in such cases. Chronic bronchitis and spasmodic asthma received much benefit from faradization of the thorax, and the dyspnœa was reduced in gravity. In two instances the paroxysms of angina pectoris were aborted by prompt galvanization of the sympathetic, the left side being selected preferably in both subjects; the relief was quicker than that following the inhalation of amyl nitrite. Hay fever has received pronounced benefit from galvanism applied as in exophthalmic goitre. The instances of advantage gained by electricity are not frequent in this distressing malady, simply because sufferers rely usually upon change of scene or climate; but enough has already been discovered to warrant a thorough trial of electricity at home before putting patients to the expense of travel, which they often find burdensome. In vaso-motor disturbances electricity plays a very important part as a curative agent. In exophthalmic goitre galvanism reduces the glandular swelling and relieves the protrusion of the ocular bulb. The method of application is to place the anode directly under the angle of the inferior maxillary bone (over the pneumogastric), and the cathode over the solar plexus, sending a moderate current for say ten minutes three or four times a week. In a few instances faradism applied to the cervical spine and pit of the stomach is stated to have been efficacious, but as the constant current is known to be successful it is unwise to waste time in experiments. In neurotic skin affections electricity plays an important rôle. The distressing symptoms of prurigo are frequently relieved by general galvanization. Some forms of eczema are much benefited by either faradism or induction currents. Acne may also be cured by local galvanization, and at present attention is being directed to the use of strong currents in ulcerative skin diseases. Cancer has apparently been checked by electrolysis, an interesting report having lately appeared in *The British Medical Journal*, from the pen of Dr. Parsons, of the Chelsea Hospital for Women. M. Darwin also reports excellent results by electrolysis in the treatment of cancer of the breast and various other tumors. The use of small galvanic couplets applied directly to ulcers has been long known. Early in the history of electro-therapeutics, static electricity was extensively used, but for a long time it fell into disuse. Some twelve years ago this form of electricity was again taken up, especially by physicians in New York and Philadelphia, and reports of successful use were published in our leading journals. It undoubtedly has a prominent place in peripheral nerve disorders, and there is reason to believe that deep-seated lesions are favorably affected through probable reflex action. As a tonic, the general electrization of the whole body by static machines is very effectual. The various hyperæsthesias and anæsthesias of the surface are amenable to cure or relief by static applications, and diseases resembling herpes zoster in their origin may also be overcome by this form of electrical treatment. Spermatorrhœa and similar debilitated conditions of the generative organs are frequently benefited by static electricity in the male, and amenorrhœa in the female is sometimes overcome by this form after failure of other means, including dynamic electricity. Saturnine palsy and writer's cramp also receive decided benefit under static treatment. As a

means of producing counter-irritation in joint troubles, such as in gout or articular rheumatism, static induction is frequently preferable to faradism. Both galvanism and faradism have decided effect in reducing febrile conditions. This is partly due to the known power of electricity to equalize circulation, the pulse being slowed in the majority of instances without, however, reducing its volume or tone. One good result attainable from the latter effect is the relief of insomnia in cases where drugs can be desirably omitted. General faradization at bedtime in fever cases not only reduces the temperature, but it has a special calmative effect of which advantage should be more frequently taken. The application can be made by the nurse or a member of the family after slight instruction. Patients thus treated are apt to have a better night, through abolition of the restlessness which characterizes typhoid conditions even when apparently asleep. There is no secondary depression induced by electricity thus employed, and as narcotics are prone to be followed by not only depression, but nausea and indigestion in many subjects, the advantage of electricity as an efficient substitute for them becomes apparent.

In diseases of children electricity obtains characteristic good results. Marasmus or general wasting and general debility without loss of muscle are readily overcome by thorough treatment. General galvanization should be used for its tonic effect and faradization of the muscle carefully practised to develop them by use without causing the patient fatigue by gymnastic or calisthentic exercises. In fact, most children are too young to permit of such exertion when affected by these disorders. Incontinence of urine, which we know to be extremely difficult to manage by drugs, may be controlled by galvanism faithfully pushed. The vomiting in cholera infantum is sometimes checked by mild faradic applications to the pneumogastric. Dyspnœa following whooping-cough, measels, and scarlet fever, and aphonia resultant from these affections is ordinarily removed without difficulty by galvanism, and in the latter symptom static electricity is extremely valuable. Dropsy following scarlatina is at times quickly reduced by localized electrization, as is œdema in either children or adults, provided Bright's disease is not present. The excretion of urinary solids is apparently promoted through local faradization of the kidneys in diabetes, whilst the volume of fluid is not increased, but, on the contrary, rather diminished in certain cases. Cystitis of children and adults is often cured by careful faradization, which tends to contract the engorged capillaries of the mucous lining of the bladder. The mucoid discharge is also, in these cases, much reduced under electrization.

SUSPENSION IN LOCOMOTOR ATAXIA.

By R. A. KINTOCH, M.D.,
CHARLESTON, S. C.

THE suspension treatment of locomotor ataxia having recently been much popularized, the method of carrying it out is important. The accidental death reported as having occurred in the practice of Dr. Vincent, of Sharon Springs, and the warning given by Dr. Hammond as to the danger attending the usual methods of proceeding, should lead to much reflection on the part of the profession.

Having had lately under treatment an intelligent mechanic (wheelwright), who was anxious to assist me in the proper management of this case, I was led to devise and adopt, with his assistance, a novel and, I think for many cases, a handy and useful method of suspension in which the danger coming of rotation of the body, while suspended, is certainly avoided. The plan has, besides, the merit of simplicity, the apparatus is inexpensive, and the patient, if not in the latter stages of the disease, can carry out treatment without aid. Not that I would recommend, however, as a rule, that suspension be practised when the patient is alone. In all cases it is safer to have assistance within reach.

The plan adopted, and to which the attention of the profession is now called, is to have the patient in the dorsal position upon a plank, the lower end of which rests upon the floor of the apartment and the upper end against the wall, so as to form with this an angle of from fifteen to twenty degrees. This will allow of the weight of the body, suspended by the chin and occiput, ensuring the necessary traction upon the spinal cord. The angle of the plank with the wall and floor may, however, be varied to suit the views of the physician as to the degree of traction required. The nearer the plank is to the perpendicular, of course, the greater will be the force of traction obtained by the suspension. The only precaution to be observed is that the plank inclines sufficient to insure its fixed position. Rotation of the body is securely obviated as long as the dorsal position upon the flat surface is preserved.

The patient is able, unless helpless from the too great advance of the disease, to manage the whole thing himself. He assumes the position upon the board, adjusts the chin and occiput slings, allows the body to descend because of its own weight, recovers himself, and takes off the weight and traction at will.

To accomplish this there is needed a smooth plank about seven feet long (length may be regulated to suit height of patient) and about fifteen inches wide. Six inches from the lower end a door or opening is cut about fifteen inches long and eight or nine inches wide. This may be square or rounded at the top. At the upper extremity of the plank is attached, by a few screws, a piece of iron, which curves over the top edge and extends five or six inches in advance of the anterior plane surface. The extremity of this iron rod ends in a hook or an eye. A crossbar of wood or iron, with an eyed bolt through the center and on a hook or a nob at each end, serves for the attachment of the usual leather bands and sling-pieces for chin and occiput, as in Sayre's suspension apparatus. Or the crossbar may be dispensed with and a simple sling made with a piece of soft stockinet material, arranged so as to form the slings for chin and occiput, and fixed to a ring so as to be easily adjusted to the hook of the curved iron rod above. Upon the anterior lateral margins of the plank are affixed two crutch-heads, high enough from

the lower end to admit of the patient putting his arms over them, and, when necessary, thus supporting the weight of his body. These crutch-heads may be affixed by movable screws, so that they can be elevated or lowered to suit patients of different height. When suspension is to be practised the patient places himself in front of the plank, which is inclined at the desired angle, and rests firmly upon the floor and against the wall. With his back against the anterior plain surface, he now puts his heels through the door in the lower portion of the plank (B) and, standing upon the transverse border of the plank that limits the door below (*b*); he puts his arms over the crutch-heads to steady himself for a minute; then, with one or both hands, he properly and securely adjusts the leather slings and shafts to the chin, occiput, and sides of the head. If preferred, some assistant may do this for him. It now only remains for him to elevate his arms, slip his feet easily off of the door-sill, and allow the body to descend so that his feet passes downward below the opening, but cannot reach the floor. Thus the body suspension is effected while rotation is impossible. After a few minutes, or when suspension is to be stopped, the arms are again dropped over the crutch-heads, the body elevated, and its weight thus taken from the head, the feet again drawn up, and the heels passed within the doorway. The legs now sustain the weight of the body, the straps are unbuckled, the headgear removed, and the patient takes position upon the floor, or may be assisted to a chair or bed.

In cases where a patient may be too helpless to use the apparatus after the manner described, it can be arranged so as to be first placed horizontal, and supported as an upright cross-frame by means of an iron bolt passing under and across the plank a little below its middle. The plank then works upon a pivot. The upper or head portion has under it either a stool or a leg attached by a hinge, and which reaches to the floor, so as to prevent the descent of the head portion. The patient is now placed upon the plank, when this is in a horizontal position. After the adjustment of the head-straps and slings, which prepares for suspension, the upper end of the plank, by means of a rope and pulley arrangement operating from the ceiling, can be slowly elevated to the necessary degree for insuring the descent of the body and, by consequence, the suspension by the head. At any given moment, the slacking of the rope causes the plank and body to resume the horizontal position, and thus arrests the suspension.

Dr. Alexander B. Mott, the well-known surgeon and physician of New York, died August 12, of pneumonia, at his farm near Yonkers.

RECENT MEDICO-LEGAL CASES.

By HENRY A. RILEY, Esq.,
NEW YORK.

THE question of execution by electricity has been under careful examination in New York before a referee appointed by the Supreme Court, to determine whether this method of death was "cruel and unusual." If it should be determined to be so it could not be used, because the Constitution expressly provides that such a method cannot be enforced. A great deal of curious, interesting, and, at times, irrelevant testimony has been presented, but the report of the referee has not yet been made, so that the public can hardly tell on which side the balance of proof lies. One strange result will probably come about if the referee and the Court both hold that the use of electricity would cause a "cruel and unusual" death, and that is the escape of the murderer Kemmeler from being put to death at all, for there is now in New York no legal mode of execution except by electricity.

This will explain the active efforts made by him to prove that electricity ought not to be used, but it hardly explains how such expensive counsel would engage in the effort for many successive days in midsummer. The explanation which many find in the long drawn out sessions before the referee is that the different electric light companies are deeply interested in the question whether their apparatus is deadly or not. If it should be demonstrated beyond a doubt that the current used by some of the companies in their ordinary service was likely to cause instantaneous death, it would lead the public, in all probability, to insist that better means be taken to isolate it, and this might be expensive. It is claimed by some companies that their apparatus is harmless, and it would be inconvenient for them, to say the least, to have it proved that it is death dealing. Hence, the active effort to prove that the alternating current is not fatal.

It is supposed that the Westinghouse Company is not pleased that its dynamos should have been chosen as the ones most likely to cause death instantly and painlessly.

Some of the testimony already presented has great interest, and should be printed for general distribution. The proof is, however, quite conflicting, and we do not see how the referee can report very decidedly for or against the use of electricity. It would hardly be according to the usual way of referees to report that he did not know anything about it, but would have to wait until an experiment had been made; but that is about the way the matter stands. The conditions under which an execution would be conducted are so different from a thunder storm that the freak of the lightning, in tearing all the clothes off a person and yet not causing death, can hardly be considered as decisive on the subject. Yet this case is one of the principal ones relied on by Kemmeler's counsel to prove that no certain results can be predicated on the use of electricity, but that death, if caused at all, would be a "cruel and unusual" one.

The question of Sunday observance and the drug stores has come up for settlement in Nebraska. It

seems that the defendant in a criminal action kept a general stock of ladies' and gentlemen's furnishing goods, notions, fancy goods, dry goods, soaps, combs, toilet boxes, canes, etc., while adjoining was an establishment where almost the same goods were also kept for sale and, in addition, a general stock of drugs, etc. The defendant did not think it was right for him to obliged to close on Sunday while his neghbor was allowed to keep open, and, under the guise of selling drugs, also sell the articles which the defendant could not sell. He, therefore, decided to keep open, and was arrested. The Court, in holding that he was liable under the charge, and that the law was constitutional, also decided that the druggist could not sell general articles of merchandize on Sunday. The only way for the merchant to protect himself seems to be to have the druggist watched and arrested if he sells anything except medicine on Sunday.

In a recent Georgia case it was held that it is within the discretion of the trial court to require the plaintiff, suing for a physical injury alleged to be permanent, to submit to an examination by competent physicians at the instance and at the expense of the defendant in the action, to ascertain the nature, extent and probable duration of the injury, so as to afford means of proving the same at the trial. The Judge stated that he could certainly admit of no doubt that in a proper case the cause of justice would be subserved by such an examination, and the decided weight of authority is that courts have such power. "As to the suggestion in argument that the rule would operate hardly upon delicate and modest females, we can only say that they would be safely guarded by the discretion of the trial judge There would be no danger, we think, in this country of an examination being ordered needlessly, or where an improper shock to modesty or feelings of delicacy would be likely. We decide simply that the power exists, and that in each case it is to be exercised or not, according to the sound discretion of the presiding Judge."

What care must a city take of the prisoners in its jails to prevent its becoming pecuniarily liable for its neglect? This was the question in a North Carolina court regarding the liability of the city of Asheville. The city, it seemed, supplied all the articles required by law to the jailers, but the latter were so neglectful or inhuman as to permit the window glass to remain broken during inclement weather, and not to supply bed clothing when in some way the previous supply had become entirely destroyed. The court held that under such circumstances if any harm came to the prisoners there was no liability against the city, no knowledge on the part of the officials concerning the neglect of the jailers having been shown.

The court ruled that this case was not like another, where the prisoner was confined in a narrow cell—eight by fourteen—located in a cellar under the market house, with no window and no ventilation, except a grate in the door that opened on an underground passage with a window at one end, lighted through a grate on the sidewalk.

The city would be presumed to know about structural defects of this kind, and consequently there would be a liability.

An English lawyer named Serjeant Robinson has recently published a volume of reminiscences of much interest and humor, and one of the incidents narrated is connected with Justice Maule, an eminent jurist on the English bench. The Justice was trying a man charged with an assault upon a female. The defense set up was consent on the part of the prosecutrix, and Maule soon made up his mind that there was abundant ground for it; but it was a question for the jury, although in summing up he pretty clearly indicated to them his opinion as to the course they ought to take.

But, as often happens, when an interesting young specimen of the other sex is concerned, juries are apt to wink at little foibles which they would not tolerate in their own.

In this instance they seemed for a long time very reluctant to adopt the Judge's view; but he generally got his own way, and having interposed with two or three sarcastic remarks during their deliberations, they at length acquitted the prisoner; whom Maule addressed in these words: "Let me, my man, give you a bit of advice. The next time you indulge in these unseemly familiarities, I recommend you to insist on your accomplice giving her consent in writing, and take care that she puts her signature to the document, otherwise it seems to me you may get before a jury who will be satisfied with nothing else."

A CASE OF OLD FRACTURE OF THE PATELLA

CURED BY WIRING THE FRAGMENTS.

By W. C. WILE, A.M., M.D.,
Ex-Vice-President American Medical Association, President of the American Medical Editors Association, Member of the British Medical Society, Editor of the *New England Medical Monthly*, etc.

OF all the various fractures of bones of the human body, there is *none* which excites more uneasiness as to the result of the healing process, in the mind of the surgeon, than does a solution of the continuity of the patella. Various devices have been advocated for the purpose of keeping the fragments in apposition, in order to have the desire of the surgeon realized—union by bone, instead of cartilage, but none of these instruments have produced the results, of which, taken collectively, we may, as a profession, be proud. To be sure, with the hooks of Malgaigne, better results have been obtained in late years than formerly, though the failures have been many and near together, while diseases of the fragments of bone have been caused by their use.

To say the least, they are cruel. Next to the hooks, come in their order plaster of Paris, mole skin plaster, bandaging, etc., *all* of which in our hands have proved unsatisfactory. To be sure, an occasional case will get well with fair results, from seemingly simple dressings, but these cases are exceptional and unusual. About twenty-five years ago the method of cutting down, and in the case of old un-united fracture freshening the edges of the fragments, and wiring them together with silver wire,

came into vogue. For a time it fell into disuse, to be again revived by that famous surgeon, Sir Joseph Lister, the man to whom we owe our deepest debt of gratitude. One thing seems to be pretty well established, and that is, by this method a greater percentage of good recoveries have been reported than by any other, and if done under strict antiseptic precautions, it is comparatively free from danger. The following case will illustrate the method and result:

John F. H., an American, forty-one years old, of bad habits, on January 23, 1884, about 5 P.M., slipped on the ice at One Hundred and Forty-eight Street and North Third Ave., New York City, and fell heavily to the sidewalk, striking his right knee. On attempting to rise he found he could not do so. An ambulance was called and he was taken to the Reception Hospital of Bellevue Hospital. At this place it was set, by means of, as he termed it, a surgical instrument and rubber plaster. He was kept there for two weeks and two days. On the Sunday evening previous Prof. Frederick S. Dennis saw him. August 31, had him put in a plaster-of-Paris splint and transferred him to St. Vincent Hospital. Here the plaster-of-Paris splint was kept on for three days, when he was taken to the operating room and Prof. Dennis applied Malgaigne's hooks. This was done without ether but with considerable pain. These hooks were kept on for six weeks and were then taken out, but not without causing a great deal of pain during their removal by House Surgeon Riley. He remained in the hospital two weeks more and then left with an ununited fracture, but still with the aid of a cane was able to crawl around. In October, 1887, he was brought to me by Dr. G. H. Pierce, of this city. I found that the bone was fractured in three pieces, that there was only cartilaginous union, and that the gap between the fragments was about two inches. His trade was that of awning maker and at it he could not work at all. In fact he was liable to fall at any time from the slightest rotation inward or outward of the foot. I advised an operation and he was removed to the Danbury Hospital where, on November 26, in the presence of Dr. Robt. T. Morris, of New York, Drs. Watson and Pierce, of Danbury, Barber, of Bethel, and Todd, of Ridgefield, I did the following operation. Thoroughly washing and shaving the parts with soap and water, aided by a nail brush, and then douching the limb with a solution of bichloride solution 1 to 1000, I made an incision (an irrigating tube playing on the wound all the time, with a bichloride solution 1 to 1000) in the median line over the patella. The incision was about seven inches long, and the skin and fascia were then dissected up. I found that the fragments were widely separated and connected only with moderately firm cartilaginous bands. These I dissected out, and with a cartilage knife I cut away enough of the bone of each fragment to make a well roughened edge. By the aid of assistants I made holes in them, and drawing them together with double silver-wire I twisted them tightly. The coaptation was perfect.

After all the sutures were in position, the ends were twisted and hammered into the larger fragments, where they have remained to this day, causing no inconvenience whatever. The débris was all cleared out, bleeding stopped, the edges of the wound brought together with silkworm gut stitches, iodoform dusted on the external surfaces, a cotton pad placed over all and a roller applied. A straight board splint was applied to the posterior surface of limb, held in place simply with a roller. The patient rallied from the shock quickly, and for ten days did not have a pain or suffer the slighest inconvenience. On the thirteenth day I took off the posterior splint, and put on a plaster-of-Paris dressing, but this caused *so* much pain that I had to remove it on the same day, replacing it with the old one taken off. The patient was kept in a recumbent position for eight weeks, when he was allowed to go about the ward. The wound healed throughout its entire extent by first intention. There was *no* inflammation of any character, and when he was discharged after three months there was firm union, the limb was strong, as he said, as strong as ever. Here certainly was a man restored to usefulness by the wiring of the fragments when several other methods had failed.

The Polyclinic.

MANHATTAN GENERAL HOSPITAL, NEW YORK.

ACUTE ENDOCARDITIS—HYDROTHERAPEUTIC TREATMENT.

MARY MORRIS, aged eight, admitted April 21, 1889, suffering two months from cough and severe pain in left chest. Whole body is cyanotic, countenance distressed; cannot sleep on account of cough and dyspnœa. Lungs normal; systolic bruit loudest at apex, transmitted to the left. Temperature 102.6°; pulse 120; respiration 60.

April 27. Very restless and fretful. ℞.—Tr. digitalis, ♏ v, t. i. d.; calomel, gr. vi. Temperature 104°; pulse 125; respiration 56.

May 1. (Service of Dr. Baruch.) Condition unchanged. Temperature 102.7°; pulse 110; respiration 40.

May 3. Area of cardiac dulness increased; apex displaced to right; systolic murmur at base. Temperature 101.6°; pulse 120; respiration 50. ℞.—Ice bag to præcordial region. Discontinue digitalis.

May 5. Temperature 99°; pulse 108; respiration 40. Considerably improved.

May 7. Temperature 99°; pulse 100; respiration 36. Ice discontinued on account of defect in bag; patient greatly improved.

May 23. Has continued to improve; discharged, cured, to-day.

SUBACUTE RHEUMATISM TREATED HYDROTHERAPEUTICALLY.

Mrs. Julia L.; admitted April 25, 1889. Had acute articular rheumatism eight months ago; recurred several times. Both knees, ankles, and wrists enormously swollen, very painful, tender, slightly red. Antipyrin and tincture of iron preceded by calomel.

April 29. Pain diminished, only on moving. Ol. gauetheria to substitute antipyrin. Hot fomenta-

tions to joints for fifteen minutes followed by cold douching.

April 30. Antipyrin, 15 grains, every three hours.

May 1. (Dr. Baruch's service.) Pain considerably diminished, swelling same. Medication continued.

May 3. Medicine discontinued. Blanket pack on entire body, with frequently repeated hot fomentations (almost dry) to the joints, until entire body was in full perspiration. This to be followed by rapid cold washing and friction.

May 8. Swelling considerably diminished, pain and stiffness somewhat increased. Continue daily pack and washing.

May 11. Swelling subsiding, pain same. Ordered wet pack followed by half-bath.

May 20. Swelling greatly reduced. Wrists still measure 10 inches in circumference; pain diminished.

June 4. Little pain except in elbow and shoulder; stiff in other joints. Wet pack continued.

June 6. Is sitting up. Wrists measure 6½ inches in circumference (a reduction of 3½ inches in seventeen days); appetite good; general appearance greatly improved.

Menstruation occurring, the cold, wet pack was discontinued, the swelling again increased, and the patient, declining further hydrotherapeutic treatment despite the evident benefit, was discharged from hospital.—*Baruch.*

PENNSYLVANIA HOSPITAL.

ERYSIPELAS.

LONGSTRETH presented a marked case of erysipelas, attended with difficulty of hearing. The patient was a large robust-looking man, about thirty years of age, and an ice wagon driver by occupation. He was addicted to drinking, and three years ago had had a severe chill as a result of exposure occasioned by over-indulgence. He then, however, was not affected as at present, which condition has also been brought about by exposure to cold, necessitated by his occupation, having been suddenly attacked while engaged in delivering ice. He was given injections of pilocarpine, and applications of bicarbonate of soda were made to his face, resembling in color a rising full moon. To the blistered parts cosmoline was applied. The professor cautioned against the use of pilocarpine where the disease is attended by pneumonia, or is due to a septic agency.

RHEUMATIC SKIN ERUPTION.

Longstreth presented a young woman, whose skin was thickly covered with rheumatic eruptions, being especially marked on the face. Her temperature ranged from 103° to 104°. She experienced pain only in the ankles. She was first given citrate of potassium, then the salicylate of soda, in tablespoonful doses. The latter was covered by glycerin, ʒss, and the compound spirits of lavender, ʒj, and water, q. s. for a tablespoonful, the salicylate of soda being readily soluble in glycerin.

BUBOES.

Ashhurst placed a patient who had three attacks of gonorrhœa, followed each time, a few months later by a swelling in the groin, and whose urine presented faint traces of albumen, on the iodide of arsenic. The professor called attention to the fact that many inguinal swellings are not preceded by gonorrhœa; such as the bubo domblet, otherwise known as the bubo of primary attack, which he regards as a simple adenitis. In painting a bubo with iodine, he recommended that it be applied not over the swelling, but around its base, since the swollen part is extra-vascular, and therefore counter-irritant effects are not obtained by painting it. In opening a bubo, he advised making the incision in the line of the long axis of the body and not parallel to Poupart's ligament, inasmuch as an incision thus made would not avail for the escape of pus when limbs are flexed.

As an application for the relief of pain in sarcomatous growths of the groin, extending from the abdominal wall, Ashhurst recommends fifteen grains of iodoform to an ounce of belladonna ointment. He stated that sarcomata, as a rule, grow more rapidly than carcinomata.

EMPYEMA.

Ashhurst brought into clinic a young lad, upon whom he was to perform thoracic paracentesis for the relief of an extensive pleural effusion. Patient had a severe cold last March, attended with a pain in the left side. There was no history of an injury, so that the development of the empyema was thought to be entirely due to a latent cause. Patient had continued to work up to the time of his admission to the hospital, and until shortly before admission had experienced no great pain. Examination of chest showed that there was a large quantity of pus in the pleural cavity. The heart was pushed considerably out of its normal position, its impulses being distinctly felt against the walls of the right chest. There was no evidence of destruction of lung tissue, though vesicular breathing was heard at the base of the left lung, posteriorly. The head of the abscess appeared to the right and an inch below the left nipple. At this point an incision was made obliquely to the ribs. Upon entering the pleural cavity there was no escape of air, showing that the lungs had not undergone any destruction. The pus was now allowed to be pumped out by the breathing of the patient, and a large quantity was thrown out. Then a second incision was made about six inches below and to the left of the first incision, and a drainage-tube was inserted, passing through both incisions so as to secure a free and thorough draining off of the pus. The cavity was washed out with a solution of the bichloride of mercury. The incisions were closed with silver sutures and dressed antiseptically. The patient's temperature had not exceeded 100°, but had run down to 97°. He had had good appetite all the time, and had made no serious complaints. The case is remarkable for its comparative painlessness in view of such an extensive extravasation of pus.

TYPHOID FEVER is said to be on the increase in New York. The Bellevue Hospital authorities report an unusually large number of patients suffering from this disease.

MR. WHEELHOUSE AND MEDICAL EDUCATION.

BEFORE the annual meeting of the British Medical Association, recently held at Leeds, the President, Mr. Wheelhouse, delivered an able and suggestive address upon the general theme of medical education. After noting the slow and labored progress made by medicine in the earlier ages, when her companions were "Arabian mythologists, astrologers, and such like visionaries," and her path lay through gloomy times of mystery and doubt, he rejoices that she has become an acknowledged power, and through the efforts of the Harveys, the Sydenhams, the Jenners, the Dupuytrens, Lænnecs, and Pasteurs, has taken her place as the companion of even the exact sciences. The wonderful advances of the last few years are not evidences that we are brighter or more industrious than our forefathers; for had they the conveniences of printing, rapid travel, and close intercommnnication, of the perfected instruments and discoveries of the allied sciences which we now enjoy, they would assuredly have accomplished the same as we have.

"Does America give birth to anæsthesia? And in what part of the world does the blessing of painless surgery remain unknown? Does Sir Joseph Lister satisfy his own mind of the infinite powers of antiseptic surgery? And in how short a period of time is his brilliant discovery the common property of every surgeon in the world?"

The physician at the commencement of the present century was usually a hardworking, industrious man, whose knowledge and practice were purely empirical with him, whose head was full of formulæ for diseases with which he was only superficially familiar. His treatment looked more to nomenclature than pathology, for he knew but little of the latter. He had his remedies for fever, tic, rheumatism, indigestion, and scurvy, and for innumerable other complaints. He was usually shrewd, keenly observant, self-contained, and self-reliant. As a student he may have been rough and uncultivated, and was certainly not required to possess any special amount of education preparatory to studying medicine. In this respect the student of the present day is his superior, but, as Mr. Wheelhouse points out, he is his inferior in regard to that practical knowledge which is obtained by years of apprenticeship.

Cases are cited where men have graduated with all the honors awarded by our great schools of medicine, who have never passed a catheter, drawn a tooth, or applied the obstetric forceps, who would be worried to distinguish a sudaminal rash from scarlatina or rubeola, and who have mistaken the undilated oz and cervix of a pregnant woman for the child's head. And yet the student of the present day is infinitely in advance of his brother of the past in scientific attainments. The modern system of education, with its vast curriculum, is, unfortunately, made shorter in years, and, to a great extent, less practical than formerly. The practical drudgery of the early-century student may have made him superficial, but the splendid array of scientific acquirements demanded by the modern student renders him more industrious and more searching. Mr. Wheelhouse would combine the good there is in both the old and new systems, and thus obtain a more complete and practical education for the coming practitioner. He

would insist upon, at least, a year's apprenticeship with some master or in some county hospital, workhouse, infirmary, or dispensary, where the beginner would meet with the ordinary run of diseases, and see them treated before he began his more elaborate studies. He would then have him attend his four years' college course, and his examinations be few, thorough, and practical, instead of being cut up as they now are and favoring the cramming process. He thinks that by holding a single, thorough examination, theoretical and practical, as the final test of ability to practice, the student would be compelled to keep well in hand all that he had learned before, and not merely dole it out, as he now does, and immediately forget it after each of a dozen or more short examinations. These views, coming, as they do, from a well-known and experienced teacher, carry special weight.

Strange to say in direct contrast to these suggestions of M. Wheelhouse, the British authorities are deliberately opposing the system of preliminary pupilage as a necessary part of medical education, and Professor Puschmann has already declared "that in many other directions this mode of entry into the medical profession is objectionable. It misleads the learner into superficiality, because it accustoms him to skim the reality of things, since knowledge and intelligence fail to enable him to reach the bottom. Moreover, the results obtained scarcely repay the sacrifice in time and trouble which they occasion the physician who acts as teacher, and still less justify the inconveniences in the treatment of disease which they bring in their train."

This discussion about the best methods of education guarantee to us the progress of our profession. The past has shown us its errors, the present will doubtless show the future those still remaining. Nevertheless we are advancing, and to hasten the time when medicine shall wear her brighter laurels, we need to improve from day to day our system of medical education.

THE METRIC SYSTEM.

A FEW weeks ago, in conversation with a member of a prominent committee for the furtherance of the metric system of weights and measures in this country, we expressed our objection to its use in our own work before it had become universally adopted, because of the many very serious blunders likely to occur when two systems were being employed in medicine at the same time. We declined to help the introduction of the metric system in such a loose, slip-shod sort of a way. Aside from any annoyances, the dangers themselves would be most positive. Even if the pharmacists were well acquainted with the system and capable of readily transmitting one set of denominations into another—not a particularly easy thing to do at any time when using powerful drugs—a fellow-practitioner less enthusiastic about the system, and therefore less likely to be perfectly familiar with it, would be decidedly handicapped if suddenly called to a case of emergency in which the metric system had been employed in the previous treatment by the regularly attending physician. The remedy in such instances would be, of course, to insist upon every practitioner being practically acquainted with the system, and the best way to insure that would be to make it universal and compulsory.

Personally, we are in favor of the metric system, and would like to see it adopted. There are many arguments in its favor.

The one often advanced in favor of Latin prescriptions, that they can be read by scientists of all nations can almost be applied now to the metric system, and, according to M. De Malarce, this system is rapidly extending. In 1887, the aggregate population of the countries in which the metric system was compulsory was more than 302,000,000, an increase of 53,000,000 in ten years. In the same year the countries with a population close on to 97,000,000 used the system optionally, while the countries where the metric system is largely admitted, though partially applied (Russia, Turkey, British India), had, in 1887, a population of 395,000,000, an increase of 54,000,000 in ten years.

The systems of China, Japan, and Mexico are decimal, but not metric. Thus, the metric system is legally recognized by 794,000,000 of people; so that only about 42,000,000 of inhabitants of the civilized world have systems which are neither metric nor decimal.

We will not dwell upon the arguments based upon the fact that, when once learned, the decimal system is easier to remember and apply; that it is less liable to cause errors in prescription writing, the line being used instead of the point, and no confusing drachm or ounce signs being employed at all; and that its quantities are more fixed and scientific than those of the English system; because these have all been dwelt upon before.

We find that the general voice of the profession, individually and through the societies, is in favor of the metric system, but doubtless many of the gentlemen decline, as we do ourselves, to be embarrassed with a double system in operation. Better a poor one that is universally familiar than the most perfect one known only to a comparative few. Our country and profession are ready for a change in the weights and measures, and it only needs some sort of constituted authority to enforce the new system.

The Government is about adopting it in its various departments of customs, with the purpose of thus giving it prestige and favoring its adoption by the mercantile and commercial world. There is no constituted body that can compel its universal adoption by the medical profession, but could not the committee appointed to revise and issue the next pharmacopœia, which will meet soon, do something in conjunction with the American Medical Association towards

establishing the system? We trust the matter will be taken up again, old as it is, and an effort made to radically institute this much-needed change in our system of weights and measures. The teaching of it in our schools and colleges, which now amount to little more than a farce, or at most a kind of elegant accomplishment, would be of some avail, for graduates would have to know it to enter into active practice. The risks attendant upon a dual system would be forever banished, and our scientific standing in this respect would be on a par with that of the other nations.

HYDROCHLORIC ACID IN INDIGESTION.

SOME very recent investigations of Boas, whose contributions, in connection with Ewald, to the physiology of digestion, and to the clinical study of its derangements, are familiar to the profession, afford valuable hints which may be utilized in the latter.

Boas confirms the findings of Munck, Fr. Mueller, Kesch, and others, that the intestinal fluids, contrary to formerly accepted ideas, possess no emulsifying property, and that such a function is rendered improbable by the almost constant reaction during intestinal digestion. There is, it is true, a considerable splitting up of neutral fats under the influence of the intestinal fluids. In normal digestion there is a preparatory duodenal digestion, a continuation of stomach digestion, which ceases only when acid chyme masses cease to flow; then the essential intestinal ferments and the bile begin to act. In those pathological cases in which an excess of acid is secreted, the stomach digestion is prolonged into the intestinal canal; the digestion of carbohydrates and fats must, therefore, suffer materially, while the albumens are easily disposed of. On the other hand, insufficient secretion of acid, and consequent too early and persistent alkalinization, may give rise to bile decomposition and to the formation of aromatic substances (skatol, indol), with a tendency to flatulence, meteorism, diarrhœa, and their consequences. In cases of defective acid secretion, the therapeutic importance of hydrochloric acid does not rest so much upon its digestive action, which in the small doses usually administered must be rather doubtful, but to its antizymotic influence. Hydrochloric acid acts as a disinfectant upon the gastro-intestinal canal. If a decided digestive influence is desired in these cases, pancreatic preparations, which in the absence of acid may act without hinderance, are indicated. These views of the true action of hydrochloric acid explain its value in checking the troublesome eructations and flatulence in nervous dyspepsia, in which irrigation of the stomach, several hours after a meal, demonstrates a perfect stomach digestion. The successful application of hydrochloric acid in these distressing cases would be inexplicable upon any other theory than that advanced by Boas, that it acts as a disinfectant of the gastro-intestinal canal.

STRYCHNINE IN DIPSOMANIA.

RECENT contributions to the literature of the subject would confirm the views advanced by Popoff, Manassen, and others, that we have in this alkaloid a valuable remedy against a disease which baffles our best directed efforts. The hygienic and moral management still occupy the most prominent place in its therapeusis, as in all other maladies the removal of the causes is here of the first importance. Physiological experiments, which are the only rational basis for correct therapeusis, have, in this instance, confirmed the empirical results. Dr. Jaroshensky has ascertained from accurate experiments on dogs that strychnine undoubtedly neutralizes the toxic and narcotic effects of alcohol; that it renders it possible, therefore, to administer large quantities of alcohol for a long period without producing the usual organic changes. He argues from these facts that a cautious administration of strychnine is of advantage in all forms of alcoholism, both as a curative and prophylactic agent. It may be administered internally or by hypodermatic injection. The latter is preferred by Dr. Albright, of Brighton (*The Lancet*, May 21, 1889), in doses of five drops once during twenty-four hours, of a solution of 1 grain to 200 drops of water. He claims to have treated nine cases of long duration and severe type, two of which had delirium tremens, with the result of inducing a positive disgust, which begun at once and continued until the patient was restored, in ten or twenty days, with improved general condition.

So simple a treatment, based, as it is, upon physiological experiments, and confirmed by the experience already reported by others, surely commends itself to our acceptance in these unmanageable cases.

Annotations.

UNIFICATION OF WEIGHTS AND MEASURES USED IN FORMULÆ.

ADVANTAGES OF AN INTERNATIONAL PHARMACOPŒA.

M. SCHAER reported to the *International Congress of Therapeutics, Materia Medica and Pharmacologie*, held at Paris, that although there has existed since 1885, a project for an international pharmacopœa, elaborated by M. de Walheim, and which was presented at Vienna, it had not yet been discussed. On principle, such a pharmacopœa could not be officially established, for, on the one hand, if it included all the drugs employed in each country, its dimensions would become too great, and, on the other hand, if any of the special drugs of each country should be omitted, it would not answer the purpose for which it was intended. However, a very practical and acceptable codex might be constructed by the unification of the characteristics, the composition, and especially the alkaloidal names of the simpler or less heroic remedies, as well as their medi-

cinal preparations. The weights, measures and names would then have to be made alike. Latin answers fairly well for the nomenclature, and the decimal system of weights and measures is now universally used, except in England and the United States.

LONG HOURS.

EVERYBODY makes use of the railway, and it is, therefore, everybody's business to see that railway affairs are conducted in the best known manner for the safety of human life.

Lately, another instance occurred, of an engineer allowing his train to run into another while he was asleep, the accident resulting in the death of several men.

Our first thought is censure of the engineer, but when the matter is investigated it will probably be found that he had been compelled to work too long at a stretch.

There is hardly any other work that requires a greater tension of the whole organism than that of a locomotive engineer. His work is consequently most exhausting, and he should have frequent rests. These men are not required to work more hours than others, bnt the trouble and the danger lies in the way in which these hours are divided. Previous investigations in accidents of similar character have shown that engineers have been compelled to labor continuously for from twelve to twenty-four hours. No words are necessary to prove the evil of this, but both words and actions are necessary to demonstrate to the railway companies that they may not thus carelessly and indifferently jeopardize human lives.

BROMIDE OF GOLD IN VARIOUS NERVOUS AFFECTIONS.

DR. GOUBERT brought before the Paris Académie a paper on a new and effectual remedy for epilepsy. Ten years experience had convinced him that a considerable number of severe epilepsies may be certainly cured by bromide of gold, in the dose of 8 to 10 milligrammes per diem for adults, and 3 to 6 milligrammes for children in solution; the maximum daily dose being 12 milligrammes. This dose almost always produced severe headache. By lessening the dose a point of complete tolerance may be reached, which includes all toxic effects. In typical migraine, bromide of gold was found ameliorative and curative, if administered in doses of three milligrammes in watery solution an hour before the two principal acids continued six or eight weeks. The attack may also be aborted by the administration of a dose of three milligrammes in its inception, repeated in an hour. Several cases of chorea have also been satisfactorily treated by Goubert, beginning with daily doses of four to six milligrammes, gradually increased every two days until the contortions were quieted. Children rarely have headache, but they become irritable.

In Basedour's disease the author obtained a rapid and satisfactory result; and he mentions the histories of three cases, treated several weeks.

PASTEUR'S PREVENTIVE INOCULATION.

Referring to M. Roux's able paper on the subject, the *Wiener Med. Blaetter* say "that while medical circles are still cool and skeptical in Germany, Pasteur's work has received widespread recognition by the highest authorities in England. The report of the Mansion House Meeting Committee, which received the approbation of Stokes, Roscoe, Paget, Lister, Horsley and others, is referred to by the *Lancet* as follows: "After all this we must acknowledge frankly that Pasteur has succeeded in rescuing a large number of human beings from a terrible death, which no one has ever accomplished before, and still he is attacked by respectable men who impute to him a character which is entirely foreign to him. Sir James Paget, Sir Joseph Lester and Prof. Horsley have, therefore, justly illustrated the thorny and yet self-sacrificing course of this modest and good man."

A very important argument for Pasteur's preventive inoculation is found in the following report from the *Bulletin Medical*. Two months ago a mad dog bit three members of a family, husband, wife and child. The man considered his superficial wound too trifling to require Pasteur's attention; but his wife's and child's injuries being serious, they were subjected to inoculation. In a few weeks the man died of hydrophobia, while the wife and child have thus far remained free from the disease.

REPORTORIAL INGENUITY.

AS knowledge of the alleged Brown-Séquard discovery gradually spreads through the country, the ingenuity of cross-road reporters to the daily press has beautifully met the emergency.

One from New Jersey tells of a quondam, decrepit old man, who, after one injection of expressed rabbit juice, took upon himself the friskiness of that gay little animal. His locomotion is now performed only by hops and jumps, accelerated on hearing a dog.

Cabbage leaves and the like afford him needed food, and at last accounts he was seen to be digging a hole in the ground with his hands.

Anotner reporter has his man acquire canine habits, and pass his time in treeing cats and in the other sports common to any healthy cur. Indeed, these so-called "reports" need be limited only by the animals not yet extinct, so that we may expect them *ad nauseam* for some time to come.

Letters to the Editor.

IN your issue of August 10, I regret to find that I am credited by Mr. Clark Bell with the extravagant statement that 70 per cent. of the patients in this hospital "could with safety be placed with farmers and others on the Belgian plan."

Mr. Bell is evidently laboring under a grave misapprehension as to my views on this question, for not only did I not make the assertion alleged of me, but I dissent emphatically from his proposition in so far as it might apply to any hospital for the insane with which I am familiar.

I shall esteem it a favor if you can find room in your Journal to publish this correction.

Yours, very truly, G. ALDER BLUMER.

UTICA, N. Y., August 21, 1889.

ABSENT UTERUS.

ON July 28, 1889, I was called to see Miss M., aged nineteen, of handsome form and attractive manners. She had never menstruated, and wished me to ascertain by a thorough examination the cause. An investigation revealed the facts that the uterus was absent, the pubes hare-lip, the labia deficient in size, vagina capacious in diameter, but shorter by an inch or more than normal, clitoris one-half average size with power of erection, mammary glands finely developed. The dome of the vagina was perfectly smooth. May 23, 1886, this young lady was brought to me from the care of a neighboring physician to be treated for retarded menstruation. Her physician diagnosed her disease as "galloping consumption." She was markedly chlorotic and suffering from mucous diarrhœa, bronchorrhœa, dyspnœa and indigestion. Food passing undigested. Twitchings of facial muscles with moments of semi-unconsciousness. Pepsin with bismuth in a short time, checked the diarrhœa, and aided by strychnine and quinine, which were in a few days added to the treatment restored the stomach to a moderate degree of digestive action. She was then placed upon the following prescription:

R.—Tr. iron mur. . . . . f℥ ix.
Tr. iodine . . . . . f℥ iv.
Fowler's solution . . . . . f℥ iij.
M.—Sig. Sixteen drops thrice daily, after meals, in wineglassful of sweetened water.

She made a good recovery within three months, except the dyspnœa, which continued much longer. I urged an examination as soon as the chlorotic symptoms had subsided, but was refused. The bronchorrhœa referred to above is frequently diagnosed as consumption. A considerable number of chlorotic girls are brought to me every year for treatment, and I find many physicians misled by this non-inflammatory bronchial trouble.

JOHN B. BASKERVILLE, M.D.

Book Reviews.

THE ANNUAL OF THE UNIVERSAL MEDICAL SCIENCE. A Yearly Report of the Progress of the General Sanitary Sciences Throughout the World. Issue of 1889. Five volumes. Edited by CHARLES E. SAJOUS, M.D. Philadelphia: F. A. Davis, Publisher.

When the first issue of the Annual was published last year, the precise and systematic method in which the thousands of quotations from the medical journals throughout the world were grouped and classified, involving, as it did, a prodigious amount of labor, called forth the highes praise and commendation from the critics and reviewers with such a degree of unanimity as is seldom achieved by any publication. Still the scope of the work was such that necessarily there was much room for improvement, and the editorial department, acting upon the many suggestions received from members of the profession interested in the undertaking, have introduced into the present issue numerous features, which not only add considerably to the inherent value of the work, but will also tend greatly towards the furtherance of its marked success. A brief resumé of these will serve to demonstrate their merits.

In glancing over the compact and elegantly printed pages of the volumes, one cannot fail to be impressed with the immense stride which has been taken towards making their issue of the Annual still more comprehensive and cosmopolitan than was the former. The fact that over four thousand quotations more than last year have been added to the vast fund of information gleaned from alll sources, largely through the untiring efforts of the corresponding staff of editors, is a worthy earnest that in the future no means will be left untried by which the work can be made one of incalculable value as a book of reference. To facilitate research, all foreign weights and thermometric measurements have been reduced to those in general use in this country, while, at the same time, they have been retained and placed side by side with the more familiar ones. Since the metric system of weights and measures is enjoying such a rapidly-growing popularity in this country and elsewhere, the adoption of this innovation will doubless be greeted with the most hearty approbation. The dates, also, of all journals, periodicals, and brochures referred to have been mentioned in the text, that still greater facility may be afforded the investigator.

An improvement which far surpasses the others mentioned, and which alone would vastly increase the value of the work, is the insertion at the close of each volume of a complete index. The great advantage which is to be thus derived is patent to all, and the addition needs but to be mentioned to be commended. At the same time, the full triple index of the work is retained at the close of the last volume, constituting one of the most attractive features of the Annual. Just here we might be permitted to suggest that some degree of interest, and, also, we believe, of value, would be added to their index by the introduction of an alphabetical list of the authors and investigators quoted, with references to the departments in which their observations have been mentioned. We merely insert this, however, as a suggestion, which we would submit to the editorial department.

The chromo-lithog.aphs, engravings and maps, of which there are thirty in all in this issue, are of a degree of excellence worthy of the standard of the work, and are valuable additions to the text, while the numerous illustrations add greatly to the interest attracted to the various departments.

Two new sections, Examination for Life Insurance and Railway Neuroses, have been given a place in the Annual for this year, their great importance, to a large proportion of the profession, demanding this new departure on the part of the editors. Climatology and balneology are thoroughly discussed, while bacteriology, which has grown into a science of itself, and a knowledge of which is now recognized

as of the utmost importance to the medical profession, is well considered. The great advances that are being made in this new field of scientific research, as shown by the reports for the past year, seem to indicate that we are upon the eve of a complete revolution in the science of medicine, and that in the near future all diseases will be classified upon an etiological rather than upon a clinical basis, while our treatment will tend towards the removal and destruction of the cause rather than towards the alleviation of the symptoms. Electro-therapeutics is likewise pressing its claims upon the profession, and while treatment by electricity will not prove the panacea which some at present seem to claim it to be, it will doubtless prove of extreme value in a certain class of cases.

In the hasty survey of the merits, or demerits, of a work of such a magnitude and scope as the Annual, necessarily many points of interest must remain unnoticed, only to become apparent upon a more careful investigation. We would remark, therefore, in conclusion, that the Annual is worthy of a careful perusal by each member of the profession, who, while too actively engaged in his business pursuits to search through the innumerable periodicals for desired information, will here find, already isolated from the mass of superfluous literature, that which he would ascertain, and in such a form as is most readily appropriated and digested.

Lesions of the Sacral and Lumbar Plexuses. By Charles K. Mills, M.D., Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic, Neurologist to the Philadelphia Hospital. Reprinted from *The Medical News*, June 15, 1889. 22 pages.

A learned discussion on the importance of grave lesions of the pelvic plexuses, including growths and other diseases of the uterus, ovaries, and Fallopian tubes; neuritis or nerve degeneration arising from pressure or bruising during labor; rectal disease; pelvic cellulitis; abscesses and tumors; and gun-shot wounds. In the diagnosis of these lesions, Dr. Mills lays great stress upon the value of close rectal examination, and upon the differentiation as to the lateral or bilateral character of the affections.

A Manual of Chemistry for the use of Medical Students. By Brandreth Symonds, A.M., M.D., p. 154. Philadelphia: P. Blakiston, Son & Co., 1889.

This is one of the best of the student's manuals upon chemistry that we have ever seen. It vividly recalls to us the lectures of Prof. Chandler, both in its arrangement and method of presenting the subject. A book of this size must necessarily be deficient as a complete exposé of the whole science, and yet so concise and orderly is its matter arranged that there is but little omitted, which a medical student would need to know. The chapters upon water and air are especially interesting and practical; those upon graphical formulæ and chemical theories present in a brief and clear manner facts which are usually among the most difficult for a novice in the science to grasp. The entire work indicates plainly the author's knowledge of what a student needs, hence we recommend it as a text-book.

Lectures on Obstetric Nursing. Delivered at the Training School for Nurses of the Philadelphia Hospital. By Theophilus Parvin, M.D., Prof. of Obstetrics and Diseases of Women and Children at Jefferson Medical College. Cloth, 12 mo., pp. 104. Price, seventy-five cents. Philadelphia: P. Blakiston, Son & Co., 1889.

It was the author's intention at first to have these lectures appear only in a medical journal, but happily he has been persuaded to issue them in book form, which the publishers have done in a manner highly creditable to the typographical art. In no department of medicine is good nursing more essential than in obstetrics, and yet many of our best authorities are deficient in that kind of instruction, which is especially useful to the obstetrician; this little volume supplies the want. In these two lectures and appendix the personality of the nurse and the proper management of the lying-in room are treated of in all their minutial; while the style exhibits the classical and literary taste for which Dr. Parvin is so well known.

Pamphlets.

A Manual of Sanitary Rules and Regulations in the District of Narragansett, Rhode Island.

Cerebral Localization in its Practical Relations. By Charles K. Mills, M.D., Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic and College for Graduates in Medicine.

This is a paper that was read before the Congress of American Physicians and Surgeons, in Washington, last year. Its size almost warrants the title of book, and the name of the author is an assurance as to the value of the subject-matter. Dr. Mills goes thoroughly over the ground laid out in the title. He begins by relating the first suggestions as to the possibility of centers of cerebral localization, and mentions the first timid and cautious operations inspired by the new discoveries; then gradually leads us along the swift path of advance made by physiologists, neurologists, and surgeons, till he reaches the present status of affairs in this most interesting and important subject.

A large number of cases are cited of operations performed both in this and other countries for various brain lesions, such history being, of course, of the greatest value as a guidance in future operations. Several cuts are given illustrating the centers thus far localized. With regard to the motor zone, Dr. Mills says: "Wonderful, indeed, is this motor zone of the cerebrum, a marvellous mosaic of centers of function, wrought from the great conceptions and priceless labors of the artists of our own guild; a mosaic, to each block, angle, and jointure of which the neurologist can point the surgeon and say, cut here or there, or touch not this or that."

On the Nature and Treatment of Epistaxis. By Alexander Harkin, M.D., F.R.C.S., Belfast,

The author believes that continued attacks of epistaxis are frequently due to derangement of the liver, and he has had excellent results in obstinate hemorrhagic diatheses by administering internally chlorate of potassium and applying a blister over the liver.

The same treatment he has used with much benefit in cases of hemorrhoids. He cites several instances in proof of the good results.

The Inception, Growth, and Work of the Anglers' Association of Eastern Pennsylvania. By A. M. Spangler, President of the Associatlon.

This is an interesting report of the work already done by this Association, and contains suggestions for the future. The name being rather misleading, the President believes that it ought to be changed, for the Association interests itself in everything pertaining to fish culture, fish protection, and fishing of every kind.

The Medical Digest.

The *Sanitary News* criticises somewhat the sulphur fumigation recently recommended for the prevention of diphtheria by the New York State Board of Health in its bulletin. Prudden has shown the exciting cause of diphtheria to be the *Streptococcus diphtherial* which is not destroyed by sulphurous acid gas. Carbolic acid and corrosive sublimate are the only germicides that have proved to be satisfactory and efficacious.

The Sympathetic Ganglia.—W. Hale White M.D. *Journal of Physiology*, July 1889. In the human fœtus the superior cervical ganglion is an organ having some function, but it begins to degenerate soon after birth and this degeneration continues till, towards the end of life, the nerve cells are atrophied and functionless. Further observations upon animals and human beings seem to prove that what is thus quite conclusively established in regard to the superior cervical and semilunal is true of all the collateral ganglia. In man the function of the lateral ganglia is maintained well into adult life and only begins to disappear in old age.

Prognosis of Cirrhosis of the Liver.—Professor Semmola, of Naples, in a clinical lecture on Cirrhosis, published in *Il Progresso Medico*, maintains that the prognosis of the disease depends entirely on the quantity of urea excreted during twenty-four hours, as he has proved to his entire satisfaction in seven cases. He teaches that increase in the secretion allows a much more favorable prognosis than a decrease. The quantity of urea secreted corresponds, according to him, with the functional activity of the hepatic cells; so that the extent of nitrogenous metabolism is proportionate to the number of normally acting cells. For the treatment of the disease Professor Semmola recommends an exclusive milk diet, which must be systematically and regularly administered.—*Lancet.*

Alleged Contagiousness of Cancer.—"A small commune in Normandy, Saint Sylvestre-de-Courcelles, with a present population of only three hundred and seventy-nine, as compared with five hundred twenty years ago, has in the eight years 1880–1887 lost no fewer than eleven of its inhabitants, between the ages of sixty-two and eighty-three, from cancer—a proportion of fifteen per cent. of the total mortality. All but one of the cases occured in males, and in as many as eight the cancer was seated in the stomach. Such facts have led Dr. Arnaudet ('L'Union méd.,' No. 52) to conclude that cancer is contagious, and is propagated through the medium of water. It is true, he remarks, that not one of the eleven persons mentioned were water drinkers, but then they drank cider, which is made with the pond water of the district. Dr. Arnaudet thinks this sufficient ground to advocate the use of antiseptics and of boiled water as prophylactics against cancer, as well as against typhoid fever or phthisis."—*Lancet.*

Cider and Typhoid Fever. — M. Olinir discovered the bacillus of Eberth in swamp water at Graville, where a typhoid epidemic is prevailing. In view of the fact that this water is largely used in the fabrication of cider and that his experiments prove that alcoholic fermentation does not modify the course of the bacillus, the question raised is an interesting one.—*La Normandie Médicale.*

Gælactorrhœa (Rosemtery).—

℞.—Distilled water	200 gram.
Simple syrup	30 "
Iodide of potassium	1 "
Metallic iodine	1 "

M.—Sig. A tablespoonful each hour.

—*Gazette de Gynéeologie.*

Senile Microbio-mania. — A savant of Naples, Dr. Malinconico, has made a greater discovery than the famous elixir of youth of Brown-Séquard. The journals announce very seriously that Dr. Malinconico is about to discover the *microbe of old age.*

This microbe is transmitted, according to the Italian savant, by inheritance, invades with age the entire human organism, ravages and destroys it, producing old age, and finally death.

Dr. Malinconico hopes that he will be able to discover the means to combat, and finally to destroy, this terrible microbe, which will prevent men growing old. The savants are invaluable!—*Revue de Thér.*

The Use of Ice.—No ice in the morning on an empty stomach. No ice before or during meals. No ice during digestion. No ice after violent exercise. No ice when the body is perspiring. No ice for women during the menstrual period. No ice for children.

Those who make use of iced drinks should be careful not to drink too much, or to swallow too rapidly. In case a sudden chilling should be experienced the danger which threatens may be averted by violent exercise. In this way the circulation may be reëstablished.

In conclusion, it may be well to remember that the avoidance of these rules may result fatally.

—*Journal de Hygiene.*

Uterine Carcinoma.—Kaltentach presents the statistics of fifty-seven cases of total extirpation of the uterus through the vagina. But two deaths followed the operation instead of two hundred and twenty-nine, which is the figure given by most of the operators. He attributes these excellent results, first to the fact that he closes the peritoneal cavity after the extirpation of the uterus, and then he is careful to abstain from the abuse of antisepsis. In reality, many operators are not content in disinfecting in advance, as much as possible, the vagina, their instrumeuts, and their hands, but during the entire time of the operation they deluge the parts with relatively concentrated solutions of liquid antiseptics, which occasion fatal intoxication in a much larger number than is imagined, as many of the cases have never been published.

SACCHARINE.—At the meeting of the Académie de Medicine, M. C. Paul made another communication regarding saccharine; after having strongly recommended it. As a sweetening substance, in doses from ten to twenty grammes a day, he brings it forward to-day as one of the best of dentifrices, as it possesses the power of arresting fermentation.

—*Bulletin de l'Academie de Medicine.*

URAL, A NEW HYPNOTIC.—This body, obtained by dissolving urethane in chloral, presents itself in the form of crystals soluble in alcohol, little soluble in water, which volatilizes without decomposing, and is fusible at 106°. It imparts a bitter taste.

Poppi, who has experimented with the hypnotic, claims that it is the most rapid and trustworthy of all that we know. It does not modify the blood pressure, and its administration is never followed by accidents. It is prescribed with success in cardiac affections, mental maladies, hysteria, etc.

—*La France Médicale.*

THE PATHOLOGY OF GOUT.—Dr. Maximin Legrand is about to publish a remarkable work upon this subject, of which the following are the conclusions:

1. The presence of uric acid in the blood and urine is physiological.

2. The excess of uric acid in the blood is inoffensive as long as elimination is not interfered with. Whenever the quantity of urine decreases at the same time as the quantity of uric acid eliminated in twenty-four hours, one may look for an attack of gout. As soon as the proportion of uric acid increases, the paroxysm is calmed. If this proportion passes the normal limits, the fit is at an end. This is the crisis of the ancients.

3. Lead, by affecting the kidney and diminishing the eliminating power of that organ, produces gout.

4. It is possible that iron may act in the same manner. It is generally acknowledged that the salts of iron, soluble and insoluble, produce in a short time an aseptic effect, and decrease the secretion of the gastric juice. They tend, therefore, to produce constipation by decreasing the enteric fluids (particularly the sulphates and the chlorides, which are the most astringent). One may presume by analogy that they constipate the kidney.

In considering that physiologists have made some researches on this subject, it is enough to know that iron favors plethora, to understand that it equally favors gout — gout which is the disease of strong men, and does not attack females until the menopause.

5. Plethora diminishes the volume of the kidney, and suppresses in part the eliminative function of that organ. Since Dr. Todd, of England, called attention to this subject, in all the autopsies of gouty subjects, the kidney is found reduced to two-thirds, and sometimes half its volume. This has been considered an effect of gout. It is, on the contrary, the cause.

6. The treatment of gout consists in establishing by every possible means the renal function.

—*Revue de Thér.*

THE experiments of Dr. Henry P. Loomis, of New York, with the so-called elixir of life, conducted with all scientific precautions, have not led to any very definite results. After deploring the newspaper notoriety given to the subject and stating what he considers to have been the true propositions of Brown-Séquard in regard to his experiments with the hypodermatic injections of testicular fluid, he says (New York *Medical Record*, August 24, 1889): "Following Dr. Brown-Séquard's instructions and always observing strict antiseptic precautions, I crushed in a mortar a small portion of the tissue of the testicle of a two-year-old ram, mingled with an equal quantity by bulk of distilled water. The resultant mixture, after infiltration, disclosed under the microscope albuminous granules and crystals of spermine that are formed of a phosphate of an organic base, but no bacteria or spermatozoa. Thirty minims constituted a dose, and fresh material was prepared on each occasion. Not more than an hour was allowed to elapse between the death of the animal and the operation."

The following are the author's conclusions:

"I. *a.* I can see no reason to anticipate danger of septicæmia from the use of the fluid prepared under proper antiseptic precautions, provided the material used be absolutely fresh and free from all trace of disease. My attention was called to the necessity for the closest scrutiny in this last particular, by having discovered, in specimens taken from an apparently healthy ram, a solitary tubercle in which were demonstrated tubercle bacilli. In none of the cases have I seen any bad results, and only in a few has there been a moderate amount of pain at the point of injection, lasting from six to eight hours.

"*b.* I can explain the singular nervous affection apparent in certain of the cases only on the theory that upon the nerve-centers the mixture exerts some powerful but as yet unexplained influence, which, even if its use be eventually proved beneficial in some cases, must render its employment in others a matter of caution. It is far from safe to say and proceed upon the belief that 'if it does no good, it can do no harm.'

"II. *a.* I seem to see in almost all the cases *old men* subjected to the experiment an increase in strength and vitality which certainly persists for several days. I have noticed nothing in the least resembling the secondary depression which so commonly follows the use of ordinary stimulants.

"*b.* When used in cases of actual disease no modification of pathological conditions or processes has been recognizable.

"I therefore conclude:

"1. That the injection of this testicular mixture does, as claimed, produce 'nutritive modification' in the tissues of elderly men, due probably to the stimulation of the nerve-centers.

"2. As far as my own experiments are concerned, sufficient time has not yet elapsed to justify an affirmation or denial of the correctness of Dr. Brown-Séquard's second conclusion.

"3. There is in the theory sufficient ground for further experimentation."

THE TREATMENT OF ECZEMA.—Dr. Unna, of Hamburg, publishes in the *Monatsschrift für Dermatologie* a paper on the Diagnosis, Etiology, and Treatment of Eczema. He says that even before the experimental cultivation of bacilli exact clinical observation had distinguished a number of entirely different types of eczema, and he thinks that each different type will be found to require a different mode of treatment. The type most frequently seen in Hamburg is seborrhœic eczema, and the parasite causing it is the same which in the first instance produces pityriasis capitis. Those persons who suffer from seborrhœic eczema of the head, including those affected with pityriasis capitis, are apt to suffer from the same kind of eczema on other parts of the skin. Dr. Unna has repeatedly pointed out that we possess a series of valuable remedies for the treatment of seborrhœic eczema in all its forms, viz.: Sulphur, resorcin, chrysarobin, and pyrogallol. Of these remedies resorcin is the best, as being the least likely to produce local or general ill effects. It may also be used in an alcoholic or watery solution, or in the form of ointment, paste, soap, or powder. Dr. Unna's favorite formula is a solution of three drachms of finely-powdered resorcin with an equal quantity of glycerin in six ounces of spirits of wine, diluted with four times the quantity of water or camomile tea. A thin layer of cotton wool well moistened with the solution is applied, covered with some waterproof material, and fastened by a bandage. These applications are particularly useful when the treatment is prolonged, or when it is carried out by night. They are, of course, impossible in general eczema of adults, but not in that of infants. Dr. Unna describes an especially important effect following the application of resorcin, viz.: a swelling of the epidermis, by which all painful fissures are healed in a single night. In order to ensure healing, he advises that the skin should be anointed after the removal of the bandage, and that washing with soap should be avoided. A few peopie suffer from a resorcin idiosyncrasy, which necessitates the immediate cessation of this treatment, and the application of powder to the affected parts. This idiosyncrasy is, however, very rare, as he has only met with it ten times in five years' observation, during which time he has seen 2000 cases. He remarks that his treatment is not adapted to those cases of long existing eczema, in which strongly-infiltrated or thickly-indurated patches occur.—London *Lancet.*

ILL EFFECTS OF ANTIPYRIN.—A young lady, aged twenty-one, has been under my care suffering from chronic ovaritis, associated with intense dysmenorrhœa. In addition to treatment by bromide of ammonium and tincture of gelseminum (which, by the way, were fairly successful in reducing the pain), I had given her some powders consisting of ten grains of antipyrin, one of which was to be taken when the paroxysms became severe. On July 25 last she took one of these (the first); about five minutes afterwards she experienced a very curious sense of heavy weight in the thorax, with a feeling of suffocation, her breathing became hurried and difficult, and there followed almost immediately a loss of power in the left side (the right side was slightly affected); in a few minutes a peculiar, very bright erythema appeared over the whole surface of the body, the patient appearing, as her mother said, "just like a boiled lobster." This rash was accompanied by a sensation of "pins and needles" down the left arm and leg; the circulation seemed to be arrested for a little while, as the rash faded to a dull purple. In a few minutes a feeling of collapse set in, accompanied by a profuse cold perspiration, and simultaneously severe vomiting began. In about ten minutes, under the influence of stimulants, all these unpleasant symptoms passed off, and she seemed to have recovered entirely. That the drug was good was shown by the fact that two or three other patients had had some quite recently from the same box, and I can only attribute the symptoms above described to an idiosyncrasy on the part of the patient.

—Thomas Winsgrave, M.R.C.S., in *The Lancet.*

A MIXED CASE OF TYPHUS AND TYPHOID FEVERS.—In a report of a case of a young man admitted into the Mater Misericordia Hospital, presenting the symptoms, on admission, of a typical case of typhoid fever, including diarrhœa and the rose-colored eruption, Dr. C. J. Nixon records that on the second day after admission the symptoms of typhus supervened—low, muttering delirium and profuse maculated eruption over the the face, trunk, and dorsal aspect of the wrists. The disease ran a rapidly fatal course, death ensuing on the ninth day after admission, the twelfth of the fever, as nearly as could be ascertained. The autopsy, sixteen, hours after death, revealed a black fluid condition of the blood, the spleen in a state of putridity, and a medullary infiltration of the solitary glands and patches of Peyer, accompanied by swelling of the mesenteric glands. Upon this latter point, together with the clinical history, Dr. Nixon bases his diagnosis of a mixed case of typhus and typhoid fever, since of the hundreds of autopsies of typhus fever in not one is there a record of any intestinal lesions, all observations showing that in that disease the solitary glands and Peyer's patches present an absolutely healthy appearance. The paper is one of especial importance.

—Dublin *Journal of Medical Science*, August 1.

FARADIZATION OF ABDOMINAL CAVITES IN ASCITES.—This treatment has been found successful by Muret (*Rev. de Med.*, September, 1888) in two cases occurring in Kussmaul's clinic, and it is confirmed by Kaufman (*Berl. klin. Woch.*, August 5, 1889), whose observations resulted favorably in ascites due to disturbance of the portal circulation in liver troubles, or diseases of the spleen, peritoneum, or in pericarditis; but not when the ascites formed a part of a general dropsy. The application offers more success when made immediately after paracentesis, because at the time the muscles may be brought into active contraction. The object aimed at is a thorough massage of the abdominal muscles, of ten to fifteen minutes duration, repeated twice daily.

Medical News and Miscellany.

It is reported that typhoid fever is at present prevalent in London.

Dr. J. G. Fritz, of Lebanon, was stricken with paralysis August 16, and died instantly.

Measles have caused death 583 times this year in Glasgow, being the severest epidemic of measles since 1871.

The School of Medicine of Boston University has graduated 478 physicians. Nearly one-half of these are women.

Complaint is being made in certain sections of the city that garbage is being hauled through the streets without the covering required by law.

A change of the time of meeting of the Mississippi Valley Medical Association has been ordered, and the meeting will be at Evansville, Ind., September 10, 11, 12.

The Royal Society of Hygiene in Italy has resolved to associate itself with the congratulation accorded by his countrymen to Max von Pettenkofer on his having attained his seventieth birthday.

The deaths of the following eminent men are announced: Dr. A. Nuhn, Honorary Professor of Anatomy in Heidelberg, Dr. Kandinski, of St. Petersburg, a well-known writer on mental diseases.

Dr. L. Webster Fox, of this city, is to be married, Sept. 4, to Miss Bickerton, of Liverpool, England. After the wedding they will make a tour of the Continent, which will probably extend to Norway and Sweden.

Dr. Eisenberg and Dr. Wiley were in Reading recently, inspecting the hospitals of that city, they having been appointed a committee by the Norristown Hospital and Dispensary to submit plans for establishing the proposed hospital.

California still continues to have faith in the health-giving properties of the eucalyptus. The State Board of Horticulture is just now distributing seeds which have been received from Australia of a large number of varieties of the famous tree.—*Times.*

The Annual Meeting of the American Dermatological Association will be held in Boston, during three days, beginning September 17. For information, address Dr. Geo. H. Tilden, 122 Marlboro Street, Boston, Secretary and Treasurer.

Several cases of typhoid have recently occurred in a town in the province of Baden, Germany, and it came to light that three of the patients first affected procured their drinking water from the same well. The water was then examined, the strictest precautions being used to prevent infection from other sources. In three days the cultures were found to have developed on an average 140,000 colonies to the cubic centimeter (about one-half cubic inch). Ten tests had been made, but only in one of these was there found a single colony af typhoid bacilli.

—*Deutsche Med. Wochenschrift.*

Dr Guerder recommends the employment of equal parts of boric acid and powdered washed coffee as a snuff in whooping-cough claiming a cure can be affected in from eight to fifteen days.—*Revu de Ther.*

A New Use for Flags.—The Medical Department of the Paris University will use a flag whenever a confinement is in progress in the lying-in wards. A blue flag indicates a simple confinement, a yellow flag a difficult labor, and a green flag that an operation may be necessary.

Some weeks ago a patient reached Wilkesbarre from Washington to be treated for an affection of the eyes, and Dr. Lampman, whom he consulted, told him his sight could never be restored. The patient was made sick of discouragement, and a couple of evenings ago died of grief.

Dr. James L. Cabell, Senior Member of the Faculty of the University of Virginia, died at Overton, August 13. Prof. Cabell was a great-grandson of Dr. William Cabell, was born in Nelson County. Va., August 26, 1813, and graduated at the University of Virginia in 1833.

Lifting the sick is a knack. After a baggage master employed at the Broad Street Station had vainly tried to lift his invalid father, a petite girl, a graduate of the Nurses' Training School of Philadelphia Hospital, came silently floating into the room, like a bit of zephyr, and gave the burly sick man just the turn he needed.

Another Local Anæsthetic.—Since the advent of cocaine, it has become quite the fashion to discover local anæsthetics. The latest is one which was introduced to the members of the Berlin Medical Society recently. Hayap is its name, and it seems to have considerable power. An aqueous solution distilled into the eye of an animal brought about complete anesthesia which lasted in various instances from ten to twenty-four hours.

A small boy sojourning on the coast of Maine sent the following clipping to his father in Boston:

Examiner: "What would you do in the case of a man with clammy sweats?"

Budding Sawbones: "Advise him to give up clams."

The boy appended the following:

"Dear papa, I thought you would appreciate the above, as you are having the sweats and I am having the clams."

Tea Adulterations for the American Market.—Consul Crowell, of Amoy, reports that a large portion of the Amoy oolong tea is poorly cultivated, picked and dried; that it is dirty and adulterated, and was called "stuff," in the last year's report of the Amoy Commissioner of Customs, who added that it "was alone wanted in America." This last, the consul says, is true; for nearly the entire crop of Amoy oolongs—bad and unfit often for use as they are—are annually marketed in the United States, and, he thinks, the American public ought to be warned and protected against this so-called tea.—*Boston Medical and Surgical Journal.*

A NEW use for rabbits has been found by the physicians of the Birmingham, England, Lunatic Asylum. A number of wild rabbits have been turned loose into the fields adjoining the institution, so that the inmates will be amused by seeing the rabbits run about, and to divert the minds of the patients is one of the great objects of the institution.

AT Marseilles, Bordeaux, and Poitiers, public exhibitions of hypnotism have been forbidden. Our Paris correspondent writes: The Department Council of Public Health advised the rector of the Academy to take this step in the districts under his authority, and he wisely followed the good advice. In Belgium, Geneva, and Mecklenburgh-Schwerin, they are likewise forbidden. In Paris, unfortunately, unwise doctors can show off their patients, and quacks follow in their steps with unwholesome imitations.

—*British Medical Journal.*

HYDROPHOBIA.—An extraordinary case of hydrophobia is stated to have occurred near Sheffield. It appears that an iron-moulder named Parkins died after several days' acute suffering, although there was no evidence of his ever having been bitten by either a dog or a cat. The doctor's opinion is that the malady was caused by the deceased having been licked by a dog on the face, at a spot where he had cut himself by shaving.—*Lancet.*

ACCORDING to the new code (non-authoritative, however) of Belgian medical ethics, a medical man on being summoned to a new patient is bound to do his best to ascertain whether any one else has been in attendance during the present illness. The simple denial of the patient is not sufficient to absolve the doctor from any further attempts to learn the truth. If it is found that some one else has been in attendance during the existing illness, the successor is bound to satisfy himself that his fees have been paid before he accepts the position of medical attendant himself. When acting as temporary substitute for a confrère, if a new patient hitherto unknown to the latter sends, the locum tenens may retain him permanently on his own list.

IT is now more than thirty years since Dr. Landarrabico called attention in the medical journals to the great value of green or unroasted coffee in hepatic and nephritic diseases. After having continued to use the remedy for upward of a third of a century in many hundreds of cases, he again appeals to the profession, through the *Moniteur de Therapeutique*, to give it a trial in those cases of liver and kidney troubles which have resisted all other treatment. His habit is to place twenty-five grammes, or about three drachms, of the green berries (he prefers a mixture of two parts of Mocha with one part each of Martinique and Isle de Bourbon coffee) in a tumbler of cold water, and let them infuse over night. The infusion, after straining or filtering, is to be taken on an empty stomach the first thing after getting up in the morning. He cites many cases of renal and hepatic colics, diabetes, migraine, etc., which, although rebellious to all other treatments for years, soon yielded to the green coffee infusion. It is worth a trial at any rate.

LAZARETTO PHYSICIAN H. B. Brustar reported to the Board of Health that, on the arrival of the American Line steamer "Lord Gough" at Quarantine, he found Eliza Schembe, one of the passengers, and a native of Finland, suffering from scarlet fever. The patient was immediately removed to the Lazaretto Hospital, and the appartment occupied by her on the steamer was thoroughly disinfected before she was allowed to proceed up the river.

THE MORTALITY OF FOREIGN CITIES.—The annual death-rate per 1000 in the principal foreign cities, according to the last weekly return communicated to the Registrar-General, is as follows: Calcutta, 22; Bombay, 24; Paris, 22; Brussels, 20; Amsterdam, 22; Rotterdam, 26; The Hague, 25; Copenhagen, 27; Stockholm, 27; Christiania, 22; St. Petersburg, 33; Berlin, 32; Hamburg, 26; Dresden, 33; Breslau, 39; Munich, 39; Vienna, 23; Prague, 26; Buda-Pesth, 33; Trieste, 23; Rome, 20; Venice, 35; Cairo, 58; Alexandria, 40; New York, 39; Brooklyn, 32; Philadelphia, 30; and Baltimore, 28.

DR. L. H. TAYLOR, of the State Board of Health, says that a week ago there were two hundred and fifty cases of typhoid fever in Wilkesbarre, and, in his opinion, the origin and propagation of the disease are due to the polluted water in the Laurel Run reservoirs, from which the city gets its supply.

The chemical examination of the water of Laurel Run does not discover the presence of any material amount of hurtful matter, but the microscope distinctly shows the presence of cesspool drainage of such character as condemns it absolutely for drinking purposes. The doctor thinks the only safe course is to condemn the present supply of water entirely.

NEW JOURNAL.—We announce to our readers the appearance of a new review, entitled: *Journal of Cutaneous and Syphilitic Diseases*, edited by Dr. Henri Fournier, with the collaboration of Drs. Buchin, Buret, Gaudin, Renouard, of Paris, Lassalle, of Montpellier, Martin du Magny, of Bordeaux, Schnell, of Marseilles, Alfred Cooper and Hugh Roberts, of London, von Duering, of Hamburg, Pauly, of Wiesbaden, Suzor, of Port-Louis, etc., etc. This publication will be of an essentially practical character, and its purpose will be to popularize in some sort dermatology and syphilography. It will be issued at Paris. We wish all success for our new contemporary.

JOHN KELLY, a coachman, has begun suit in the Common Pleas against Dr. J. C. Guernsey to recover damages for personal injuries received on December 1, 1888, on Twenty-second Street, below Race. Mr. Kelly was in the employ of the doctor, and was, it is stated, in the habit of driving the physician around the city in his visits to his patients, but that on this occasion the doctor himself insisted on driving the horse, a spirited animal, and the consequence was that on account of alleged negligent driving the horse ran away and the plaintiff was thrown from the buggy and was badly injured about the head and legs. Mr. Kelly brings suit for the injuries received.

—*Ledger.*

THE Medical Society of Pennsylvania will hold no meeting this year. On accunt of the great calamity at Johnstown, and for other reasons, it has been thought expedient to adjourn the Convention until June 10, 1890.

THE first Annual Meeting of the American Pædiatric Society, will be held in Washington, D. C., on September 20 and 21, 1889, under the presidency of Dr. A. Jacobi, of this city. The sessions will be held in the Johns Hopkins Hospital, Baltimore, Md., by invitation of the director of the hospital. Papers are announced by the President: A. D. Blackader, Montreal, Canada; W. D. Booker, Baltimore, Md.; Dillon Brown, New York; A. Caillé, New York; Charles Warrington Earle, Chicago, Ill.; J. Henry Fruitnight, New York; Francis Huber, New York; A. Jacobi, New York; John A. Jeffries, Boston (by invitation); H. Hoplik, New York; Thos. S. Latimer, Baltimore, Md.; I. N. Love, St. Louis, Mo.; Arthur V. Meigs, Philadelphia, Pa.; J. O'Dwyer, New York; Wm. Osler, Baltimore, Md.; A. Seibert, New York; H. N. Vineberg, New York; W. T. Northrop, New York; J. L. Smith, New York; and V. W. Vaughan, Ann Arbor, Mich.

THE New York *Sun* says that twelve medical students found a suite of rooms on the top floor of an east side building, which they divided into sleeping apartments and study rooms. They were comfortably housed and excellently, though plainly fed, at a cost of $3.33 each, per week. They exchanged among themselves the costlier books of reference necessary for their studies, and organized themselves into a society. Rigid discipline was maintained, and a duty was prescribed for every hour of the day. In the evening and early morning they were regularly quizzed by one of their number specially selected each week for that purpose, upon the lessons of the coming day, and the spare hours were devoted to study and review. Among the members there were three honor men in the examinations, last spring, and there promises to be several more of the same class at the end of the winter's season.

IN the Societe de Biologie, Fere affirmed that a dying person in his last moments thinks of the chief events of his life. Persons resuscitated from drowning, epileptics with grave attacks, persons dying and already unconscious, but momentarily brought back to consciousness by ether injections to utter their last thoughts, all acknowledge that their last thoughts revert to momentous events of their life. Such an ether injection revives once more the normal disposition of cerebral activity, already nearly extinguished, and it might be possible at this moment to learn of certain important events of the past life. Brown-Séquard mentions the remarkable fact that persons who, in consequence of grave cerebral affections have been paralyzed for years, get back at once when dying, their sensibility, mobility, and intelligence. All such facts clearly show that at the moment of dissolution important changes take place, reacting upon the composition of the blood and the functions of the organs.—*Medical Zeitung*.

THE LOST STOMACH.

With a face that was full of care,
With his hat too small for his head,
The club man sat in a big arm chair,
And these were the words he said:
"It's O, that the awful truth
Is that little I can digest;
And it's O, for the stomach of sturdy youth
That did'nt want ease nor rest!

"It is O, for the good old time
When nothing a pang could bring.
When the maw I managed was in it's prime
And could wrestle with anything;
When the pie or the pickled beet,
Boiled cabbage or biscuit hot
To assimilate was a simple feat—
But the stomach that was not!

"Time was when a rich pate
Was a source of supreme delight,
And my head was of normal size next day
Though I drank like a fish at night;
But it's gone!" With a face of care,
With his hat too small for his head,
The club man sat in a big arm chair,
And those were the words he said.

—*Western Medical Reporter.*

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 20, 1889, to August 26, 1889.

BAILY, JOSEPH C., Lieutenant-Colonel Surgeon and Medical Director. Leave of absence for one month is granted. Headquarters Department of Texas, San Antonio, Texas, August 12, 1889. S. O. 54, Headquarters Department of Texas.

POPE, BENJAMIN F., Major and Surgeon. Leave of absence for one month, with permission to apply through Division Headquarters for an extension of two months is granted. Par. 7., S. O. 55, Department of Texas, August 17, 1889.

Commanding officer at Jackson Barracks, New Orleans, La., telegraphs the Adjutant-General of the Army, that HARVEY E. BROWN, Major and Surgeon, died to-day, at 1.40 o'clock, P.M.

Changes in the Medical Corps of the United States Navy for the week ending August 24, 1889.

SCOFIELD, W. K., Medical Inspector; HIBBETT, C. T., Passed Assistant-Surgeon. Detached from the "Lancaster."

WHITE, C. H., Medical Inspector; HESLER, F. A., Passed Assistant-Surgeon Ordered to the "Pensacola."

CURTIS, L. W., Passed Assistant-Surgeon. Ordered to the "New Hampshire."

JONES, W. H., Surgeon. Detached from the "Pensacola," and placed on waiting orders.

VON WEDEKIND, L., Assistant-Surgeon. Detached from the "New Hampshire," aud ordered to the "Pensacola."

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service for the two weeks ending August 24, 1889.

LONG, W. H., Surgeon. To proceed to Gallipolis, Ohio, as Inspector, August 7, 1889.

WHITE, J. H., Passed Assistant-Surgeon. Granted leave of absence for thirty days, on account of wound, August 16, 1889.

CONDICT, A. W., Assistant-Surgeon. Detached from Revenue Bark "Chase," and ordered to Louisville, Ky., for temporary duty, August 19, 1889.

GROENEVELT, J. F., Assistant-Surgeon. Ordered to South Atlantic Quarantine Station for temporary duty, August 8, 1889.

Medical Index.

We purpose in this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Acute intestinal obstruction, medical treatment of, Gray. Kansas Med. Jour., August, 1889.

Antiseptics in surgery, McClintock. Kansas Med. Jour., 1889.

Astigmatism and presbyopia in children, early detection of, Engstadt. N. W. Lancet, August, 1889.

Acute Multiple Adenitis, Langmaid. N. Y. Med. and Surg. Jour., August 12, 1889.

Affections of the spinal cord, suspension in the treatment of, Shaw. Atlanta Med. and Surg. Jour., August, 1889. Also in St. Louis Med. and Surg. Jour., August, 1889.

Arsenic, the Chemistry of, Hills, Boston Surg. Jour., Aug. 15, 1889.

Beitrag zur verebung der hypospadie, Lesser. Archiv. für Pathologische Anatomie uver für Klinische Medicin, 1889, Heft 3.

Bemerskung überdie vater-pacinischen köiperchender gefässwand shoma. *Ibid.*

Beiträge zür hypnotischen therapie, Michael. August 8, 1889.

Obstetrics, two unusual cases of, McHaltern. Atlanta Med. and Surg. Jour., August, 1889.

Obstruction and gangrene of the intestine; laparotomy; death, Briggs. Occidental Med. Times, August, 1889.

Correcting the whole error of refraction and the necessity of using a mydriatic, Cotter. Atlanta Med. and Surg. Jour., August, 1889.

Cellular abresiæ of the nymphæ, Logan. Canadian Practitioner, August 1, 1889.

Compound triple dislocation of the left astragalus, case of, Gott. Med. Record, August 10, 1889.

Concussion of the spine in its medico-legal aspects, Smith. Jour. Am. Med. Association, August 10, 1889.

Chronic glaucoma, an analysis of ninety cases of, Bull. N. Y. Med. Jour., August 10, 1889.

Cocaine hydrochlorate, the toxic effect of, Chetwood. Med. Record, August 10, 1889.

Creosote in phthisis, a clinical note on the use of, Newcomb. Med. Record, August 10, 1889.

Cocarpisin, Morgan. Indiana Med. Jour., August, 1889.

Chronic arthritis of the knee, Altis. Med. Bulletin, Aug., 1889.

Crepitant râle, the, Jackson. Med. Standard, Aug., 1889.

Cerebral symptoms connected with phthisis. Boston Med. and Surg. Jour., August 8, 1889.

Copaiba n dentistry, Rollins. *Ibid.*

Double pneumonia with abscess of left lung, report of a case of, resulting in recovery, Lewis. Weekly Med. Review, August 10, 1889.

Ein fall von Gastritis catarrhalis chronica cystica proliferans, Langerhaus. Archiv. für Pathologische Anatomie und Physiologie und für Klinische Medicine, 1889, Heft 3.

Erosions and ulceration of the os uteri, a formula for, Jonson. Southern Clinic, August, 1889.

Electricity in gynecology, Davis. Atlanta Med. and Surg. Journal, August, 1889.

Emphysema, McKee. Cincinnati Lancet-Clinic, August 17, 1889.

The etiology of typhoid fever, Crawford. Western Med. Reporter, August, 1889.

Epilepsy, some general considerations in the treatment of, Church. Western Med. Reporter, August, 1889.

Eye surgery, needless and annoying restraint in, Chisolm. Jour. Amer. Med. Assoc., August 17, 18889

Electricity, the therapeutic uses of, Shoemaker. *Ibid.*

Foods, drugs, and their adulterations, report on. The Boston Med. and Surg. Jour., August 15, 1889.

Fever, Burnham. Med. Standard, August, 1889.

Forms of crime, development of the, Fulch. The Open Court, August 8, 1889.

Hydronephrosis and renal atrophy, especially as resulting from functional disturbances of micturition, Edes. Medical News, August 10, 1889.

Hernies, a cure radicale des, Marsil. L'Union Médicale, Aout, 1889.

Typhogenic coccogenic and bacillogenic sycosis, Unno. St. Louis Med. and Surg. Jour., August, 1889.

Hysteria, a case in which symptoms of, were associated with those of aubillar lesion, Cordell. Maryland Med. Jour., August 17, 1889.

Insanity and allied affections. Maryland Med. Jour., August 17, 1889.

Is it advisable for the State of Michigan to return to the County the care of the insane. Amer. Lancet, August, 1889.

Klei nere mittheilungen, Stricker. Archiv. für Pathologische Anatomie und Physiologie und für klinische Medicin, 1 Juli, 1889.

Modern obstetric methods, Townsend. Med. Bulletin, Aug., 1889.

Neurotic or hysterical fever, King. Med. Record, August 10, 1889.

Normal and abnormal nervous activity, the influence of climate and season upon the manifestation of, Platt. Med. News, August 10, 1889.

Nature's book, man's chapter in, Dedmon. Southern Practitioner, August, 1889.

Ophthalmology, report on the advance in, Fryer. Kansas Med. Jour., August, 1889.

Obstetrics and Gynecology, notes on, McKee. *Ibid.*

On œdematous form of disease of septic œdema of the upper air passages. N. Y. Med. and Surg. Jour., August 10, 1889.

Peripheral paralyses due to carbonic-oxide poisoning, Jacoby. N. Y. Med. Jour., August 17, 1889.

Patella, a case of compound fracture of the, treated by wiring, Armstrong, N. Y. Med. Jour., August 17, 1889.

Plutories et harpogi dissecti dialogue anatomisches gedicht aus dem anfang des 16 jahrhunderts, Roth. Archiv. für Pathologische anatomie und Physiologie und für klinische Medicin, 1 Juli, 1889.

Practische winke ofer guajakolin jektionen, Schetelig. Deutsche Medizinal-Zeitung, August 5, 1889.

Pine belt, the, of New Jersey, Platt. Med. News, August 10, 1889.

Pelvic peritonitis from Crede's method, Munn. Med. Standard, August, 1889.

Prophylaxis of puerperal eclampsia, Doering. *Ibid.*

Predental hemorrhage, Hintermann. *Ibid.*

Quarterly review on diseases of children, Nesbitt. Canadian Practitioner, August 1, 1889.

Retro-catheterization in the treatment of urethral stricture, Lewis. Weekly Med. Review, August 10, 1889.

Sanitation, Stephens. Southern Med. Record, August, 1889.

Syringomyelia, Church. Med. Standard, August, 1889.

Summer diarrhœa of the insane, Alexander. *Ibid.*

Scirrhous carcinoma of the bladder, Kennedy. Med. Record, August 10, 1889.

Tubercular osteomyelitis of tibia, two cases of, Jelks. Jour. Amer. Med. Ass'n, August 10, 1889.

Totlich veilaufende puerperal krankungen venersacht durch die thränensack blennorrhœ einer h-famme, Loeb. Deutsche Medizinal-Zeitung, August 5, 1889.

Tuberculosis in sleeping cars, Whittaker. Cincinnati Lancet-Clinic, August 17, 1889.

Ten consecutive laparotomies, Hardon. Atlanta Med. and Surg. Jour., August, 1889.

Two incomplete ovariotomies, a report of, Buchanan. *Ibid.*

Treatment of burns, the local use of ice or cold in the, Carpenter. Amer. Practitioner and News, August 17, 1889.

Ulcer of the small intestine with perforation, Hutchens. Weekly Med. Review, August 10, 1889.

The Times and Register.

Philadelphia Medical Times. Vol. XX, No. 574. NEW YORK AND PHILADELPHIA, SEPTEMBER 7, 1889. The Medical Register. Vol. VI, No. 140.

Clinical Lecture.

A LECTURE ON VARICOCELE.

(Delivered at the College of Physicians and Surgeons, Chicago, Ill.

BY G. FRANK LYDSTON, M.D.,
CHICAGO, ILL.

PART II.

[Concluded from page 411.]

THE *treatment* of varicocele in its milder forms is palliative in character. The application of cold to the part, the use of electricity, and the wearing of a close-fitting suspensory bandage, are the principal local measures to be advised. The rules already suggested in the lecture upon sexual hygiene should be rigidly enforced, and the patient should be instructed to a certain extent in the physiology of his sexual apparatus, such instruction being absolutely necessary if you would keep the patient from the clutches of the quacks. He should be informed that the affection is perfectly inocuous, and will, in all probability, entirely disappear after marriage, and in case it be practicable, he should be advised to marry at an early date. If the varicocele be associated with nocturnal emissions or spermatorrhœa, it may be necessary to adopt some of the measures of treatment advised in the lecture upon these conditions. It is advisable in all cases in which the patient is inclined to be hypochondriacal, or suffers from neuralgic manifestations, to occasionally pass a cold steel sound into the urethra. The results of this simple treatment are often surprising, the morale of the patient being improved to a wonderful extent. Such results are explicable by the effect upon the mind as well as upon the local physical condition. Constipation requires the use of mild laxatives. Slothful habits of life should be corrected and proper exercise advised. If the patient be debilitated, tonics, such as iron, strychnine, and the mineral acids should be given. Theoretically, ergot is of service in such cases; hæmamelis has also been endorsed as a remedy for varicose veins in various situations, and seems to have a more marked action upon the venous walls than does ergot. It is a favorite remedy of my own in passive congestions of various kinds, and I usually administer it in varicocele where treatment is required, but operation seems inadvisable, or is declined. The use of the suspensory bandage, cold and electricity, with the general measures already advised usually relieve the symptoms produced by the milder forms of varicocele and prevent an increase in the size of the varix; but in the more severe cases the characteristic changes in the venous walls, due mainly to their loss of tone, or to connective-tissue proliferation, goes on, and we have as a result considerable enlargement of the spermatic plexus with its attendant discomfort. In the more marked cases the physical deformity that the varix occasions may give rise to considerable annoyance, as is illustrated by one which will presently be cited. In these cases the suspensory bandage fails to prevent a noticeable degree of deformity, and does not satisfactorily allay the various disagreeable symptoms; its failure to relieve the patient's mental condition is especially evident, for in removing and ap-

plying his bandage he is made painfully cognizant of his deformity. The knowledge that he is unlike other young men, as regards his sexual apparatus, has a peculiarly demoralizing effect upon such a patient unless he is unusually indifferent. For such cases then we must advise some more effectual means of relief than are afforded by the ordinary measures of palliation.

The various radical operations for varicocele which involve interference with the veins are, as is well known, more or less dangerous to life and to the functional integrity of the testicle of the affected side, and the surgeon ordinarily prefers to avoid all dangerous operative procedures where practicable. Indeed, many surgeons disclaim the necessity of an operation for the relief of varicocele in any case.

The late Dr. Van Buren was considerably prejudiced against operative procedures in this disease, judging from his expressions in regard to this point at his public clinics. Dr. Keyes alludes to this conservatism on the part of his late associate in his recent revision of their joint work upon Genito-urinary Diseases. It must be confessed that the disease may be temporized with in by far the larger proportion of cases. When, however, the patient suffers from the amount of mental and physical discomfort experienced by many of the cases that present themselves to us for treatment, something should be undertaken for his relief. An additional indication for operation lies in the danger of traumatic or spontaneous rupture of the diseased venous walls and the consequent formation of hæmatocele, which is a serious affection when involving these parts. There is a popular idea that the danger of fatal hemorrhage in operations for varicocele is very great, and as a consequence of this there is a tendency on the part of different surgeons to either temporize with the affection or turn the case over to instrument-makers to have suspensories applied. The proportion even of severe cases presenting themselves for operative treatment is very small.

A number of operations have been proposed for the radical cure of varicocele. One of the early operations was that of Vidal de Cassis. This method is familiar to most surgeons, and consists in passing an iron pin through the scrotum, so as to pass between the vas deferens and the enlarged veins. A silver wire is then passed alongside the pin in such a manner that the veins will be included between the pin and the wire, after which the wire is made fast to the pin at each end and the pin twisted so as to bring a certain amount of compression to bear upon the veins (enroulement). This twisting is repeated every day or two until the wire has ulcerated through the veins, after which the pin becomes loosened and is removed. The veins are in this manner cut across and occluded by inflammatory adhesions.

Prof. T. M. Markoe's modification of Vidal's operation consists in dispensing with the pin and passing the silver wire in such a manner that it forms a loop enclosing the veins, after which the ends of the loop are clamped to a lead plate upon the surface of the scrotum; the wire is tightened from day to day until the veins are severed and the loop is free, when it is removed.

An operation, devised by Mr. Henry Lee, is performed as follows: "A segment of the anterior portion of the scrotum is excised, the veins exposed and temporarily compressed. The varicose vessels are then excised, and their cut extremities seared with the hot iron."

These various operations are apparently simple of performance and devoid of danger, but, as a matter of fact, they are very often complicated, difficult, and attended with considerable risk. Unless great caution is observed hemorrhage with consequent scrotal hæmatocele may occur as a consequence of imperfect occlusion of the veins, and there is always more or less danger of exciting phlebitis, with the attendant risks of septic infection, embolism, etc. It is, also, by no means impossible for even surgeons of considerable experience to include the vas deferens in the loop of wire, an accident which will inevitably be followed by atrophy of the testicle, and may result in fatal tetanus as a result of peripheral irritation in this important structure.

A case once occurred in this city in which the surgeon accidentally ligated the vas deferens in operating on varicocele with the result of inducing atrophy of the testis. Atrophy of the testicle, after the ligation of the spermatic veins does not, however, necessarily imply that the vas deferens has been included in the ligature, for such a result may ensue from simple interference with the nutrition of the organ consequent upon the obstruction of the return circulation. Mr. Lee's operation, if done under careful antiseptic methods may yield excellent results, but there still remains the danger of atrophy of the testicle, although there is little danger of accidental ligation of the vas deferens from the fact that the operation comprises exposure of the vessels instead of their ligation in the dark.

Dr. E. L. Keyes[1] has devised an operation comprising subcutaneous ligature of the veins with silk. His remarks upon the subject are as follows: "Since perfecting the new operation, the subcutaneous use of silk, I have operated upon a great number of cases; no patient has been detained in bed more than ten days, many not more than five, one only forty-eight hours; no accident has happened. The first (catgut) cases did not get well. Catgut does not answer. The last (silk) cases all got permanently well. I have had no abscess, only the escape of a little serum in two cases, possibly a little sero-pus in one, which I did not personally attend. I now look upon the operation as one of the smallest importance, and one capable of yielding such marked benefit, that I do not hesitate to recommend it in any case of any material varicocele, which yields discomforting symptoms. I have never seen any approach to this catastrophe (atrophy of the testicle) when all the veins of both sides of the vas deferens were ligated by the method I am about to detail. That atrophy may not come on, if all the veins are tied up, I am not able to affirm, but if all the large veins are selected out and ligated in two masses, one on each side of

[1] New York *Medical Record*, September 18, 1886, and November 26, 1887. Also "Genito-Urinary Diseases."

the vas deferens, atrophy in my experience does not come on. I generally apply only one ligature, high up. I have frequently also applied another on the other side of the vas deferens, or posteriorly; sometimes I apply two on the same outer side of the vas deferens, one high up, the other near the globus major. I have prepared the silk—the common twisted silk of good size so strong that it cannot be broken by the power of the hands—in various ways; but recently I simply boil it for a few minutes to purify it and get the kinks out, and put it in a bottle containing pure alcohol. It keeps indefinitely, and is always ready for use without further preparation. I have devised and used no less than six different needles for facilitating the operation, but of late have come to use a modification of Reverdin's needle. The needle, as modified, is simply a straight needle in a handle. By a mechanism in the handle the eye of the needle is opened and shut, and by a spiral spring which I have applied the eye is kept permanently closed, so that while manipulating the handle the eye cannot be opened as may, and occasionally has happened in the original Reverdin needle during careless handling.

The Operation.—The scrotum is washed in a bicloride solution of 1 in 1000; the patient stands beside the bed so that if he becomes faint, as he often does after the puncture, he may be at once placed upon his back in bed, and the operation continued in that position. The distended veins are separated by manipulation from the vas deferens, which can be easily felt among the elements of the cord, and are moved toward the outer side of the scrotum. A needle taken from the bichloride solution and armed with one strand of silk is made to transfix the scrotum between the veins and the vas deferens. When the eye of the needle emerges, the silk is drawn through with a tenaculum and disengaged from the eye of the needle. Now the punctured scrotum is traversed independently by the needle and the one strand of silk. The scrotum is again washed in the bichloride solution and the needle withdrawn partly until it clears the veins, but it is not withdrawn out of the point of actual puncture in the scrotum. The veins are now allowed to rejoin the vas deferens and the point of the needle is again advanced upon the outer side, under the dartos, and made to emerge posteriorly at the exact point out of which the silk is protruding. The eye of the needle is now opened, the silk placed in it, and the instrument entirely withdrawn, carrying the silk with it. The scrotum is again washed, a few hairs are plucked away from the posterior point of puncture in the scrotum, and the anterior ends being firmly held the scrotum is pulled away, so that the shred of dartos included in the loop by the posterior puncture may be pulled free from the integument. Now, a few more hairs are plucked out at the anterior point of puncture, that they may not be tied in, and the silk is forcibly tied. I make a triple knot for security, cut the ends short, and let the knot shrink into the scrotum. No bleeding occurs. Any drop of oozing may be covered at the punctured points with iodoform or iodol. The dressing is simply a little cotton and a suspending sling. If other veins are to be ligated on the other side of the vas deferens, the puncture should be made during the erect position of the patient. The washing and final ligation may all be done after the patient lies down. An anodyne is usually not necessary, I really give no medicine, except a laxative on the third day; some pain and swelling follow. As soon as the patient can stand erect, without considerable pain, he is allowed to go about. The swelling gradually subsides; the hard spot at the ligated point certainly remains for a year, possibly longer, after all the affected veins are ligated; I have as yet seen no complication. If pus should form, which I hardly think possible, if proper care has been used, it must be let out by incision and treated according to its necessity.

My experience with Dr. Keyes' operation is limited to a single case, in which I had an excellent result. But I am free to say that I consider it to be open to the same objections as characterize the other operations to which I have alluded. As far as atrophy of the testis is concerned, it is certainly quite as likely to produce it as any other operations involving ligation of the veins. It seems to me that we are hardly warranted in performing operations of the nature of those described until some safer method has been tried.

In amputation of the redundant scrotum, an operation originally devised by Astley Cooper, and revived of late years through the efforts of Henry, of New York, we have recourse to a measure which is far safer than the numerous radical operations, and, if properly performed, one which yields uniformly good results. Even in the event that in extreme cases we may be compelled to repeat the operation after the lapse of years, or even if the patient be compelled to wear a suspensory bandage for the remainder of his life to obviate the possibility of recurrence of the trouble, we will have answered all the indications in the case, and more especially the relief of the deformity and the sexual hypochondriasis. The Astley Cooper operation, then, so long neglected, is, as modified by Henry, a perfectly practicable means of relieving varicocele, and should be performed in preference to all other operations for this purpose. "The fear of hemorrhage that existed in the minds of many," says Henry, "is now set aside by a perfect success following the operation." Although in my own experience I have met with but one case in which apprehension, or even any great degree of annoyance, has been caused by hemorrhage, and which in this case was due to a moderately well-marked hemorrhagic diathesis; there has been a special tendency to venous oozing in some of my cases, which has led me to modify the operation somewhat to obviate the disturbance of the wound caused by the effused fluid. In the first two illustrative cases which I shall present, the details of the Henry operation were in the main followed, the old form of clamp, however, being used. In my later operations I have modified the dressings somewhat, with apparent advantage. Instead of simple interrupted sutures of silk, I now use chromated catgut for the interrupted sutures, with silver pins, and the figure-of-eight silk suture at the

points of extreme tension, and at intervals varying with the amount of tension present or anticipated. Sutures of interrupted silk between the points are not objectionable, but where convenient the catgut is to be preferred. The number of sutures should be sufficient to accurately approximate the cut surfaces. I find the silver pins much more trustworthy in cases characterized by extreme tension—and, indeed, the tension is always great if a sufficient amount of scrotal tissues be removed—than any form of suture, whether of wire, silk, or catgut.[1]

I find that the use of adhesive plaster in the first dressing may be advantageously dispensed with. Adhesive straps are, however, of great service after the sutures and pins have been removed. As a substitute for plaster, I find graduated compresses to be all sufficient in supporting the parts. These compresses may be made of carded oakum or borated cotton. After closing the wound I wash the surfaces with a warm solution of the bichloride and dust the edges with powdered iodoform. Prior to closing the lower angle of the wound I insert a drainage-tube of decalcified bone, which substance is preferable to rubber. The wound having been properly cleansed and the edges approximated and sprinkled with iodoform, a piece of oiled silk, dipped in the bichloride solution, should be laid along the edge of the wound to prevent the superimposed dressings from sticking to it. Over the whole is placed a quantity of borated cotton in such a manner that compression will be exerted upon the space of the scrotum thus supporting the wound. The dressings are retained in place by a large square of muslin, after the fashion of a diaper, through which a hole has been cut for the penis. When a movement of the bowels occurs the bandage is removed, the dressings being supported by the hand of the patient while the bed pan is being used. Should the wound gap after the sutures are removed, an excellent method of retaining the edges in apposition during cicatrization is as follows: Thick mole-skin adhesive plaster is cut in strips of sufficient length to pass well down over the remaining scrotal tissue on to the thighs, and to approach within half an inch of the edge of the wound upon each side. Through the wound borders of these strips punctures are made and a stout silk ligature passed through, shoe-string fashion, in such a manner as to enable the surgeon to lace the edges of the plaster together, and thus secure support and apposition of the edges of the wound.

It has been my experience that those cases in which healing by granulation rather than by first intention occurs, do better in the end from the fact that the inflammatory thickening and cicatricial contraction of the scrotum yield a firmer support for the varix. A speedy union is very desirable, as the patient is usually anxious to get about, and the slower the method of healing the greater the danger of inflammatory complications.

The most important point in the performance of amputation of the redundant scrotum for varicocele is the amount of tissue to be removed. Henry's remarks upon this subject are very comprehensive: "Regarding the amount of scrotum to be removed, I can only say, take away all that is not absolutely necessary to form a covering for the testicles. There is no danger of removing too much if the clamp be properly and skillfully applied, and sooner or later there is more probability of a second operation being called for to remove more tissue."

I can heartily indorse this statement of Henry's. I have observed that even in those cases in which the remaining portion of the scrotum is seemingly scanty at first, the tissues will soon accommodate themselves to the testes and yield all the room necessary.

As the use of drainage-tubes in the operation of varicocele has been mentioned, I desire to state that my experience has seemed to show that drainage is an essential element of the operation, being indicated by the tendency to extreme tension from imprisoned blood. The primary hemorrhage in these cases is usually slight on account of the pressure of the clamp, but after this is removed and the wound has been closed there is a tendency to passive oozing of blood and serum, which may accumulate in considerable quantity, and even cause separation of the edges or giving away of the sutures. The same laxity or lack of tone of the vascular walls which predispose to varicocele gives rise to the passive oozing which causes the trouble in such cases. This oozing is, perhaps, never dangerous to life, but it would seem to constitute an important complication of the operation, and one which should be guarded against. A drainage-tube not only prevents accumulation of blood, but it facilitates the application of styptics in case hemorrhage soould be excessive.

In my earlier operations I used a hot saturated solution of boracic acid for washing the wound, but I am now using a solution of the biohloride.

[1] Henry also advocates the use of silver pins. I had used them, however, prior to the publication of his remarks upon their advantages, and I believe that they have been frequently used by different surgeons in the old method of operating.

Original Articles.

THE FUTURE OF MEDICINE.

(Read before the Alumni Association, June 13, 1889)

By WM. T. PLANT, M.D.,
Professor of Pædiatrics in Syracuse University.

MR. CHAIRMAN AND FELLOW-ALUMNI: My subject is the Future of Medicine.

When we reflect on all that has transpired to exalt our profession and bless humanity within the memory of men not yet retired from active practice, we ask ourselves whether any future period of like duration can be so prolific of discoveries and inventions, or whether, indeed, there is anything of consequence left for the coming doctors to find out.

Certainly the half century that has given us in ether and chloroform a complete mastery of pain; that has wellnigh revolutionized medical practice by teaching us more of pathology, of the self-limiting quality of disease and of the *vis medicatrix naturæ*, than we knew before; and whose discoveries in chemistry and refinements in pharmacy have completed the revolution; that has brought electricity

into such subserviency that by it we are able to amputate and remove tumors and nævi and infuse new life into palsied muscles; that has given us in the hypodermic needle an agent invariable for the quick relief of pain and other purposes; and the aspirator, an instrument that more than almost any other, except the modern obstetrical forceps, makes us proud of our ability to relieve distress; and the little but indispensable clinical thermometer; and Esmarch's bandage by means of which an amputation may be as bloodless as the lopping of a limb from a dead tree; that has conferred upon us through Sir Joseph Lister the ability to make ovariotomies and laparotomies and operations of every name and kind without pus and in large degree without danger; that has given us the pulley and weight for broken thighs and the plaster jacket for bowing spines; that has taught us how to resect joints and ribs, and how to keep the closing larynx open by O'Dwyer's tube; that has given us such remedies as cod-liver oil and the bromides, salicylic acid and cocaine, and the good twin *aunties* pyrin and febrin—to say nothing of sulfonal and spartein, and ten thousand other things that make up the success of medical and surgical practice — certainly the fifty years that has brought all these things forward has good reason to be proud of its record.

But the end is not yet. The profession, whose business it is to so study and master all agencies, both material and immaterial, as to make them subserve its lofty purposes of preventing and curing disease and improving the condition of the race, needs the ages for its perfecting. And when we consider that the workers were never so numerous and well equipped, and that the spirit of research was never so active as now, we must conclude that many new and good things are still before us. We may not, of course, forecast all our future, but some one has said, and I am optimist enough to believe it, that "everything that ought to happen is going to," and so there are some things that we are justified in predicting will come because we feel that they ought to come. A few of these I shall now speak of:

1. As to keep well is better than to be sick and get well, so the prevention of disease will be more and more the aspiration and achievement of medical science. In this respect we shall merely carry forward to completion the work already well begun. Quarantine stations, to which even now we owe a debt of gratitude for so great immunity from pestilential disorders as we enjoy, will, through the advance of medical knowledge, become so complete in their appointments, that germs from devastating epidemics in other countries will find it no easy matter, small though they are, to effect a lodgment on our shores. Boards of health have but just entered on their careers of usefulness. In the future that is just before us every State, city, and township will have its health board made up of medical and other men, qualified by special study for advising and directing in matters of concern to the public health. With such officers in every town and city, when an epidemic, of typhoid for instance, breaks out, the cause will be immediately and intelligently searched out and stamped out. If smallpox or yellow fever or cholera appears anywhere, the vigilant and capable health board will so hamper and hem it in by restrictive and repressive rules and regulations that it will die then and there for lack of forage.

There can be no doubt that important discoveries for the prevention and control of many diseases are reserved for future investigators. We can hardly suppose that smallpox is the only malady that can be forestalled by some such procedure as a vaccination. Though Pasteur's enthusiastic attempt to ward off hydrophobia by inoculation may not be crowned with the success that we all have wished for it, yet it may well be that the principle of inoculation will in the future be found to be of greatest value in preventing some other disorders that are now but little under our control.

The prevention of sickness in infants and children is especially desirable. From their susceptibility to morbid influences and the slight resistance that is bred of immaturity, infant mortality is at all times high. In one direction at least, we are able to predict a change for the better. As all attempts by medical treatment to prevent a large infant death-rate in cities during the hot months have failed, the coming remedy would seem to be the removal of the infant population—at least the bottle-nursing part of it—from the city to the green hills and the ocean shore. A "fresh air fund" charity ought to be, and doubtless will be, organized in every populous town, and thousands of little children that without such charity would yearly be swept off by inflammatory diarrhœa will be saved for future citizenship.

2. It cannot be doubted that many changes for the better are yet to occur in the medical treatment of disease. Acquaintance with our indigenous materia medica is not by any means complete. It is probable that in many plants there reside remedial properties of a high order that await discovery.

Chemistry in its wonderful onward march is every year giving us more and better tools for our work. We may believe that many valuable remedies are yet to be found in and separated from complex substances by the analyst, and that many others of known atomical composition will be synthetically produced in the laboratory.

We like to indulge the hope that discoveries are before us that will enable us to grapple successfully with cancer and leprosy and other affections to which we have hitherto been obliged to attach the hopeless prefix of incurable.

3. The bacteria question is at present the most prominent one before the profession, and is full of promise. That many diseases are caused by microörganisms appears to be a pretty well-established fact. This being so, to prevent their production, or to destroy them, would be to prevent or cure the disease to which they stand in a causative relation. To do this without, at the same time destroying living tissues, or even the whole patient, is impossible by any means or methods now within our ken. That is one of the problems for the future to solve, but with so many able and enthusiastic workers along this line, we may well be sanguine of brilliant results at no distant date.

4. I believe that we may dimly discern the dawning of a new departure in the treatment of consumption. Thanks to the great German, Koch, we now know the direct cause of the disease; and if we could destroy the bacillus by means that would not harm the patient, nothing more would be needed. Cod oil and the hypophosphites and out of door living have already accomplished something. Still, the death-rate is so high—not far from one-seventh of all deaths reported from all causes the country over—that any scheme that has in it a reasonable prospect of reduction is worthy of serious attention. More and more, as the results are made evident, the climatic treatment of phthisis will recommend itself to the profession and the public. The fact, for I am sure it is a fact, will everywhere become known that a large proportion of the chronically consumptive can be restored by going—not to Florida, not anywhere along the Atlantic seaboard—but to the elevated regions of some of our far Western States, where the atmosphere is cool, rarefied, sunny, and stimulating, if they can go early, live comfortably, and remain long. Colorado, New Mexico, and some of the contiguous States have a typical climate, probably the best in the world, because the exceedingly pure and rarefied air is inimical to the life of the tubercle bacillus. Every year those of us who are in general practice see numbers of patients with incipient lung trouble whom we would gladly send to this elysium for consumptives. But the cost of getting there, and the cost of living there, make it impossible, except for the few who have large means at command. Of these, some go too late to receive any benefit; others, from lack of home comforts and congenial companionship, become homesick and dispirited, and return before receiving the help that a long sojourn under other conditions might have conferred. What most consumptives need is encouragement to make *seasonable* change of climate; financial aid in reaching a chosen place; a cordial welcome to a cheerful home on arrival, and funds for support until so far advanced towards recovery as to be self-supporting. In our vast domain there are great and increasing numbers of wealthy and generous people who love to spread out their benefactions and make their bequests where they will do the most good. For many years the ever widening streams of benevolence have been flowing towards hospitals for the sick, asylums for the aged, and blind, and insane; towards homes for the friendless and institutions of learning, and it is not the least of the glories of this century that so much philanthropic work has been done in these various directions. But suppose our profession should bring before these benevolent people convincing evidence that an annual saving of thousands of lives could be effected through the establishment in the States mentioned of homes for comsumptives, can any of us doubt that a stream of benevolence would soon be turned in that direction also? This seems to me a matter so desirable and so feasible that I am inclined to think that some action looking to the climatic treatment of consumption on a large scale will be taken in the not distant future.

5. Is it too much to hope that some much needed reformations will soon be brought about in our American medical schools? Chief among these desirable things is a more thorough investigation of the character and attainments of those who seek admittance at their portals. Not many of our schools have now even the form of an entrance examination. Some have the form without the substance. To ask an aspirant for future membership in a learned profession to bound his native county and state; to define a noun; to work out a sum in long division; to repeat a little of the multiplication table; to give the name of our chief magistrate, and to write his own, is only playing at examination. The candidate may pass that and more in the same time, without being properly prepared to begin the study of medicine. Nor is the case much bettered if in addition—I here quote from a recent announcement—the applicant is required to translate *a passage* from one of the first four books of Cæsar's commentaries or an equivalent, that is, *one passage* from some other latin author. To those who know nothing at all of the classics, one college of medicine actually offers to teach the student, free of extra charge, the required wee bit of latin. Now, the truth is, when a young man is examined as to his fitness to begin medicine, the school should seek chiefly to know whether, besides a fair English education, he has general culture, an aptitude for requirement, a will to work and a fixed purpose—for these are the qualities that compel success always and everywhere. There are many such youths who know nothing of the classics. If one is a mechanic, able of his own head and hands to plan and construct a modern dwelling, and to do it expeditiously, economically, and profitably to himself; or a young farmer who has shown such knowledge of tillage, of due rotation of crops and marketing his produce as to both improve his land and reap a profit; or if he has been a successful teacher of a village school, such a one with a good backing of moral character and bodily health has the culture and the other qualities that make the best preparation for medical study and practice even though the classics, desirable as they are, have found no place in the preparation.

The medical college of the future will have a standard of admission; a standard so much higher and broader than that of to-day, that it will give slight heed to the presence or absence of the smatterings of a dead language.

6. Again the day is not distant when medicine will everywhere be taught, after a properly arranged and consecutive method. This is "a long felt want," and it is to the shame of the profession that the colleges have not been coerced by the withdrawing of its patronage, when argument and persuasion would not move them, into the adoption of a sensible and satisfactory curriculum. So long as the great majority of students attend on institutions that hold fast to the old pernicious, hotch-potch custom of our course of lectures once repeated, so long the profession must deplore the fact that the majority of its members have not had the educational opportunities that ought to have been provided for them.

But the present outlook is hopeful. Already a

number of colleges have adopted the graded system and all the others must sooner or later fall into line.

In this reformatory work this school has the proud distinction of having been a pioneer. Glancing back over its history to 1875, when a graded course was formally adopted, one cannot but think that if, as we are told and as I believe, there is holy joy and comfort in sacrifice made for principle, this college ought to feel joy and comfort beyond expression.

7. Not only in the happy future will all the schools follow a systematized curriculum, but the length of the undergraduate course will be considerably extended. The one great aim of a medical college should be to make good physicians. There is hardly a school in the land that does not stop short of this. The field of medicine is so broad that in a three years course one may lay a good foundation, but the superstructure must be incomplete. The preparatory work ceases before the student is made into a competent and ready practitioner. A young doctor who has not had time and opportunity to examine patients, and many of them, at close quarters, can hardly be a good diagnostician. He cannot be skillful and ready in prescribing, or expert and handy in surgical operations and dressings, unless at some time in his educational course it has been his daily habit to do these things. He cannot feel and show himself at home in the sick room, unless he has been there before. Every spring, thousands of young people go out as graduates from our American colleges who must spend years in private practice before attaining to that familiarity with disease and that skill in the various medical and surgical procedures that they ought to have had before being graduated. A few days ago I received a letter from a former student of this school, one of the very best of the many good men it had sent out, from which I make this extract: "I do not complain of my college, but I do most bitterly complain of the system in this country which will let a man go out so unprepared for his work as a course limited to three years must necessarily do. Graduates are not to blame, for few of them suspect until they have tried it that they are unfit for their work."

If these things are conceded to be true, it follows that the preparatory course ought to be lengthened to four if not five years. The last year or year and a half will be given largely or entirely to hospital and dispensary work, and in applying, under wise guidance, the knowledge gathered from books and lectures during the previous three years to the examination and treatment of patients. Thus, the hospital of the future will, besides the care of patients, serve as a working laboratory for advanced students of medicine.

8. In the future, laboratory work will have a more prominent place than it now has in medical teaching. That it will do away with the time honored didactic lecture is not probable. Each has it uses and each is the better for the aid it receives from the other. The friends of this and other schools have sorely felt the need of greater facilities for laboratory instruction; but it will not always be as it has been. Sometime there will be a more general appreciation of the fact that the medical school is not second in its capacity for usefulness to any other educational institution whatsoever; and of the other fact that to achieve the best results it must be generously dealt by. When that time comes schools of liberal and fine arts and theology will not be the only college beneficiaries of noble men and women of wealth. In the medical schools chairs will be endowed; histological, anatomical, physiological, pathological, chemical, and even bacteriological laboratories will be liberally equipped and sustained, and the poor medical teacher will receive some compensation for his labor.

The signs are auspicious of that "good time coming." Already the College of Physicians and Surgeons, of New York, has found its Vanderbilt; Bellevue has found its Carnegie, and the University school its Loomis, as our own splendid College of Fine Arts has found its John Crouse, and may we not cherish a confident hope that this college of medicine will yet soon find some generous friend who will come to its aid with a munificent endowment. It only awaits such aid to enter on an enlarged career of prosperity and usefulness such as its best friends—friends like Professors Hyde and Pease and Porter and Wilbur, all of blessed memory, have hoped and labored for.

9. In the medical Utopia that is just before us the diploma of the school will not be a license to practice. With few exceptions the income of teachers depends on the number of students attending and the number graduated. Besides, every good teacher comes to have a strong interest in, and friendship for, those who have been under his instruction. He knows the obstacles each has had to contend with, the difficulties to surmount, and it is a grief and disappointment to him if any fail of graduation. No one who knows men would expect that college professors would always hold themselves superior to considerations of both self interest and friendship.

As the safety of society requires that licenses to practice should be granted only on evidence of fitness, the examining body should be an impartial one appointed by State authorities and invested with State jurisdiction. Nothing, it seems to me, would do so much to break down and obliterate sectional lines and unify the profession and so much for the betterment of the schools themselves as the adoption of some fair standard of medical attainment, up to which all graduates of all schools must come before they may undertake to practice within the State. If the navy and the army has each its own rigid examination for those whom it commissions to treat sailors and soldiers—all males and all adults—should the State do less for its wives and mothers and children, to say nothing of its men? Several States have already taken the licensing matter into their own hands; when all shall have done so a great forward move will have been made.

THE West Philadelphia Hospital for Women has completed the first month of its existence, and the management expresses much satisfaction with the results already secured.

DOUBLE AMPUTATION—COMPLICATIONS.

By A. P. FRICK, A. A. Surgeon, U. S. A.,
FORT SELDEN, NEW MEXICO.

ON May 6, 1888, about 4 o'clock P.M., a Mexican, aged twenty-four, at Selden Station, was struck on the head by the cab of a backing locomotive and thrown under the wheels, which passed over both legs, nearly severing them from the body. There were also two lacerated wounds of the scalp. I was called immediately. Hemorrhage from the crushed and torn arteries was temporarily arrested by compression above the knees. The free use of aromatic spirits of ammonia and whiskey soon rallied the patient sufficiently from the severe shock of the injury to admit of the administration of ether. He yielded to its influence in twenty minutes without excitement. Six ounces were required at first, and four more continued the anæsthesia forty minutes.

Under approved antiseptic precautions, including carbolic spray, and bichloride irrigation, I was enabled to commence the operation about one hour after injury.

The left leg was crushed high up, and the upper articular end of the fibula torn from its socket.

Owing to the contused and lacerated condition of the soft parts, it was impossible to obtain a sufficient covering without sawing off the tibia above its tubercle, which was done.

With a view to the patient's best chances for recovery from the successive shocks of the accident, and of the double amputation, this lowest point possible for ablation was selected. The method chosen for this leg was antero-posterior flaps.

The right leg was next amputated, at the lower part of the middle third, by the circular method.

In both stumps, after complete arrest of hemorrhage (under irrigation with bichloride solution 1 to 1000), medium sized drainage tubes were laid, and the flaps brought together by interrupted sutures. The parts were then again bathed in bichloride solution, and well dried.

Iodoform powder was thickly dusted over the parts, and an ample quantity of absorbent cotton and antiseptic gauze neatly applied and bandaged.

In the after-treatment, slight secondary hemorrhages or oozings occurred from both stumps, necessitating redressing on the second and fourth days. These were done under the utmost antiseptic precautions, and both stumps were then aseptic.

No further redressing was needed until the ninth day, when ill-conditioned pus came through the drainage-tubes. Offensive odor, low vitality, and cyanosed appearance of the parts suggested danger ahead. In response, however, to the antiseptic measures taken, which included carbolic spray, an 8 per cent. solution of chloride of zinc, and permanganate solution grs. iij to ℥j, a healthy, aseptic condition was once more obtained as early as the fourteenth day, when iodoform dressings were again applied. The patient's temperature, from May 7 to 15, ranged from 99° to 101⅔°. After this the morning temperature became normal, but the evening rise continued above 100° for some days longer.

An important complication was local and constitutional syphilis. It is believed that the continued abnormal temperature was due to syphilis, and not to septicæmia, as might have been inferred from the temporary septic condition of the wounds. The fact, moreover, that, coincident with antisyphilitic treatment, there was a prompt reduction in temperature, is corroborative of the belief that the long continuance of fever was due to venereal, not traumato-septic infection. Both Wythe and Erichsen write of an elevation of temperature, from one to two or three degrees, on first occurrence of the second stage of syphilis.

Strength was maintained by quinine, sherry wine, with fluid extract of wild-cherry, and a liberal nutritious diet. During the period of low vitality ammonia carbonate was also given.

About the nineteenth day, the patient's condition being otherwise excellent, there occurred a synovitis in left knee. I had rubber tubing coiled into a mat, laid it over the affected knee, and passed ice-water through the tubing on the siphon principle.

In response to this simple device, for the application of cold without moisture, the inflammatory condition soon subsided; and afterwards effusion was readily absorbed under the external application of iodine.

In the operation, I had no professional assistance; but the aid rendered by A. G. Heyl, Hospital Steward, U. S. A., was efficient.

Thirty-two days after operation, I turned the case over to the authorities of the A. T. and S. F. Ry. Co. (in whose employ he had been) in a very satisfactory condition.

When last seen by me, more than a year after operation, the stumps were everything that could be desired, never having given the patient the slightest trouble; and flexion and extension of the left stump were perfectly satisfactory, affording the very best conditions (after amputation just below the knee) for the use of an artificial limb.

Synovitis was unquestionably due to amputation through cancellated bone tissue so near the joint; and, so far, justifies precautions given in books against the amputation above the tubercle; but its easy control and all the other very satisfactory results prove that, in this case at least, the saving of the knee-joint by choice of such operation was not only justifiable, but judicious; since, besides giving a better and more useful stump, it was, in all probability, far safer than any operation higher up would have been.

CASE OF EXTENSIVE BRAIN LESIONS WITH ILL-DEFINED SYMPTOMS.

By JOHN J. BERRY, M. D.,
PORTSMOUTH, N. H.

MRS.—, aged thirty-four, had in December, 1888, an attack of paralysis of the left arm which, she stated, was recovered from in about a week. Prior to that time had been perfectly well. An imperfect history of syphilis, but otherwise nothing in personal or family histories worthy of record. Present attack began July 15, 1889, and consisted of a sudden and partial paralysis of the right arm. None elsewhere. Her condition at date of first observation, was as follows: temperature 99; pulse 90 and weak. Lies in a semi-conscious condition but can be readily aroused. Articulates with difficulty but can be easily understood. Memory impaired, hesitates for words but uses them correctly. Mental action sluggish. Comprehends perfectly well everything that is said to her. Pupils somewhat dilated but of equal size. Deglutition somewhat impaired. Occasional diplopia. Can walk short distances but with difficulty, apparently from loss of power of coördination. No paralysis or anaesthesia of lower limbs. Left arm likewise normal. Considerable loss of power in right arm, though it can be moved by the patient in all directions. Some anæsthesia here as well as in central portion of right cheek and side of head and right side of tongue. The latter is protruded with difficulty but nevertheless in a straight line. Complains of a constant and severe pain in the occipital region, greatly increased by motion, though not affected by rotation and concussion. Is inclined to sleep the greater part of the time and while quiet, is apparently comfortable. During the week preceding her death, there was noted rapidly increasing prostration but no additional symptoms. The temperature ranged from 99 to 100.5°, and the pulse from 80 to 120. During the two days preceeding death, complete aphasia, but mind unaffected. Increased dilatation of both pupils, but right much the larger. Incontinence of urine. Was not comatose but became gradually unconscious and died August 13, 1889.

Examination of the brain showed extreme congestion of its veins and sinuses. Thickening of the dura, with adhesions of the pia mater along the longitudinal sinus, in its anterior fourth. In the anterior lobe of the right side there was an area of softening about three by two inches in diameter, extending from the surface of the superior and middle convolutions downwards, about one and a half inches and into the white substance. It extended from near the extremity of the frontal lobe backwards, nearly to the anterior extremity of the lateral ventricle. The condition was evidently of some weeks standing, as there was no trace of coloring matter in the degenerated mass, whose central portion was in an almost liquid condition. Another focus of disease was found in the white substance of the middle lobe of the same side. This was a blood-clot about one inch in diameter lying in the radiating white substance, just back of the fissure of Rolando and within and above the Island of Reil. It was about one and a half inches from the surface and at a point corresponding directly above, to the posterior central convolution. The color of the clot was somewhat lighter than normal, and there was some staining of the white matter about its circumference. It was evidently of recent origin, and probably dated from the time of the second attack above noted.

Few portions of the brain possess more ill-defined functions than the convolutions of the frontal lobe of the right side, especially those portions nearest the longitudinal fissure. Yet so extensive a lesion in this locality, involving both white and grey matter, might be reasonably expected to declare itself by well-marked symptoms. The same should hold true in the case of the second lesion, which was also situated in the motor tracts and which should have produced a complete paralysis somewhere. For similar reasons, the lesion of the right arm is somewhat unique. Although small areas in the same localities have produced a similar condition of the right side, I know of no very extensive softening or hemorrhage in these portions of the right hemisphere which have failed to produce paralysis on the left side. No less remarkable is the fact, that at the time of death, the left arm which was involved in the first attack, showed a perfect recovery both as regards motion and sensation.

Hydrotherapeutics.

By S. BARUCH M.D.
Attending Physician New York Juvenile Asylum and Manhattan General Hospital.

III.

HYDROTHERAPY IN TYPHOID FEVER.

IN pursuance of our proposal to shed all the light obtainable from all sources at our command upon the important question involved in hydrotherapy, we desire to refer to the description of Prof. Fuerbringer's paper on Typhoid Fever, read before the Berlin Medical Society, a synopsis of which was published in a recent issue of THE TIMES AND REGISTER. We are moved to this step because the discussion brings into bold relief the idea we have endeavored to impress upon the profession, that a *strict adherence to the principles and methods of hydrotherapeutics is the single road to success in the application*, as illustrated by the contrast between the results of a lukewarm and a methodical bath management.

Goltdammer avows himself an advocate of a mild water treatment; his true status is already shown by the remark that "we are not in position to wipe out the mortality of typhoid fever as the cold water enthusiasts claim." This ironical allusion to Brand and his followers places him among those practitioners who, protesting against the energetic cold bathing, whose triumphs cannot be "wiped out," are nevertheless willing to order an occasional cold bath to reduce the temperature when it threatens to rise at a dangerous point, but otherwise treat typhoid fever on the expectant plan.

Fuerbringer, on the other hand, while insisting on "a methodical cold bath treatment, emphasizes the object of the bath to be less an antipyretic than as a

stimulating and refreshing agent to the nervous system, to promote cleanliness, arouse the appetite, and combat hypostases."

Goltdammer says: "There are always 10 per cent. left to die in every epidemic; the height of mortality is entirely dependent upon the occurrence of complications. There are at present no remedies by means of which complications may be avoided or cured."

If there is one point in typhoid fever treatment that has been brought out more clearly than another, it is the fact that an early and methodical cold bath treatment prevents the complications which are the chief lethal factors.

We need only to refer to the able papers of Vogel, of Munich, whose exact records, obtained from the Military Hospitals during a period of fifteen years, have established the fact, which is corroborated by the observations of Brand, Juergensen, Tripier, and others. that the early adoption of the strict cold bath treatment lessens the number and diminishes the severity of complications. As an example, may be adduced two hundred and fifty cases, reported by Vogel, in which "it was never necessary to resort to opium or bismuth for diarrhœa; meteorism, with tense abdominal wall, was observed only in cases received late; bloody stools were noted only twice; peritonitis not at all."

Goltdammer's dictum that there is no method by which fatal complications may be avoided, rests, therefore, upon lack of experience with early, strict cold bathing. Indeed, it is disputed by Ewald in the discussion referred to, and even his assertion that there is no method by which complications can be cured is gainsayed by the statistics of the "methodical cold bath" advocate, Prof. Fuerbringer, who states that only three cases out of nine intestinal hemorrhages proved fatal, and that three undoubted intestinal perforations, with peritonitis, recovered.

It may be asked why Prof. Fuerbringer did not succeed in preventing these serious complications, "thromboses, with extraordinarily protracted course, peritonitis, with and without perforation, severe nephritis and cystitis, psychoses and hemorrhages? The answer is contained in his opening words: "Whosoever would cast a glance at the most unfavorable quality of our typhoid cases in general, whoever has seen how many patients are only unloaded into our institution for the purpose of dying, will understand why I regard a mortality of 10 per cent. as favorable—indeed as a figure which approaches the possibly attainable minimum.

The fact that most of the cases were brought into hospital long after the period (the fifth day) at which prevention of complication is said to be assured by the cold-bath treatment, according to Brand and other followers, explains the occurrence of complications in the hands of a man who fully comprehends the aims and possibilities of a methodical water treatment.

A glance at the statistics of these two eminent clinicians, obtained from the same epidemic, in the same city, furnishes a lesson, with which our readers will not fail to be impressed.

Prof. Fuerbringer, who, besides nutrition, uses the cold bath to *refresh the nervous system*, etc., lost 10 per cent. of his 155 severe cases, while Goltdammer, who regards nutrition as the chief indication and regards the cold bath as a secondary therapeutic measure, lost 20 per cent. of his 72 severe cases.

The difference between the timid bath practice of Goltdammer and the bold practice of Brand, Vogel, Glenard and Tripier determines precisely the difference in their mortality percentage. The difference in the methods of bathing of various practitioners is correctly measured by the indications they aim to fulfill.

The physician whose object is to render the patient comfortable with a view to a strictly expectant course, will be content with cold sponging. This method, however, is utterly inadequate as a means of preventing complications or moderating the course of the fever.

The physician, whose chief goal is the reduction of temperature, will resort to ice-cold compresses, to the ice coil, or to an occasional bath with the addition of medicinal antipyretics. This method, too, is utterly inadequate, as has been amply demonstrated by statistics.

If, as all are agreed, our therapeutic efforts should be in the direction of maintaining the vital powers, we have in the methodical cold-bath treatment the most effective means to accomplish the end, because it not only reduces the debilitating temperature, but it *refreshes and vivifies the nerve centers which preside over the functions* upon whose integrity depends the nutrition of the patient.

Any one who has observed the bright countenance, the clean tongue, sharp appetite and good digestion of an average typhoid case under the strict cold-bath treatment will be imbued with the enthusiasm to which Goltdammer refers so ironically.

Clinical observation must decide this question of typhoid fever management. We propose to weigh such observations fairly in our columns and allow our readers to draw their own conclusions.

The technique of typhoid fever treatment will receive attention in the next article.

Paris Letter.

THE INTERNATIONAL CONGRESS.

PARIS the last few weeks has been full of medical experts of all nations and all kinds. We do not find, however, after attending all the various meetings that anything very new or original has been produced by this gathering of the nations in Congress. The first Congress held that bore any relation to medical science was that of Public Assistance, or medical charity it might have been called. A good deal was said here in regard to hospital construction and management and also about how medical charity ought to be dispensed. M. Monod stated that the principle accepted by the Government was, first, that public medical assistance was to be allowed to all indigent persons who were proved to be without physical means to carry on their existence. These are, first of all, three great classes: 1. Infants. 2. Ill

people. 3. The infirm and old. In Europe, it is considered that the government of each city or town has to see that these people get medical assistance by supplying hospital accommodation for them, and by paying physicians to attend to them. In France, at least, this is done by public assistance, and private hospitals are almost unknown. An interesting point was brought up by M. Bourneville in regard to the education of hospital nurses and infirmaries. The Paris hospitals had for years been under the control of sisters of charity of various religious orders, but the new republican city council are radical in temper and turned all the sisters out of the hospitals, replacing them by ordinary servants of both sexes. This has led to the establishment of schools to teach the young hospital aids how to apply bandages, and above all how to make effective use of the antiseptic system in use. It is an idea that might be well adopted in all American cities, so that an intelligent set of hospital aids would always be on hand as needed, and the diploma or certificate of such schools be accepted as a passport to such places. In England these schools exist in considerable number. St. John's Society gave as many as 280,000 diplomas to nurses of both sexes, according to its last report. In London, there are not only schools in each hospital to teach the servants, but also separate institutions where instruction is given by competent physicians. It is in some ways even a fashion among the better class of people in England; even ladies of the best classes like to show a first-class nurse's certificate, and a princess of the royal family is president of a nurses society. Certainly it is a good object to have competent and effective well-instructed nurses and men who understand the best methods of hospital work, and it is a method of instruction that should not be disdained even by our medical colleges and professors.

THE INTERNATIONAL CONGRESS ON ALCOHOLISM

was the next one, but the subject is not directly medical, so that we shall only refer to it briefly. Some of the points made are, no doubt, important. Dr. Drysdale, of London, showed that suppression of alcohol would have a most favorable effect on the duration of human life, and life insurance statistics prove that persons who abstain from alcohol live on an average some six years longer than those who indulge in the flowing bowl. One means used in some countries (Holland) to diminish alcoholism is passing a law that only a certain number of liquor dealers will be allowed to a certain population. This is on the principle that the temptation to drink is greater, according as the opportunity exists. In one case it is proved that the consumption of alcohol has diminished where the number of dealers have been restricted, and it augments elsewhere.

A hygienic point was raised by M. Gonse, who said that it was the duty of temperance societies to construct and keep up bars, selling temperance drinks near all the large centers of labor. Healthy drinks should be placed by them at a low price in the hands of the working population.

THE INTERNATIONAL CONGRESS OF THERAPEUTICS AND MATERIA MEDICA.

This Congress was well attended. The representive of the United States of America was Dr. Williams, of Boston, who presided over one of the meetings. Prof. Semmola, of Naples, opened the sittings by a brilliant speech in French; he also presented, during the Congress, a number of communications of considerable interest. One on Chromocytometry, as applied to alterative medication, seems of great importance. It is often difficult to determine, in treating syphilis, just exactly when we should cease giving mercury, and, indeed, there are often cases when we doubt that we should use mercury at all. An exact measure can be taken in all these cases by a comparative examination, hemoscopic and hemometric, before commencing the specific treatment, and during its use. The number of red globules and the proportion of hæmoglobine are in constant relation with the biological action of the mercury, and vary according as the mercury is acting in a healthy or in a syphilitic organism. Before the treatment the chromocytometric examination must be made, to regulate after proceedings, and it must then be repeated every three months. If the proportion of hæmoglobine increases, the indication to use mercury continues; if it falls, then the patient has had enough, and it must be stopped. This measure is good in all cases where mercury is used, as we must always fear the deglobulizing action of the drug. Dr. Semmola uses Bizzozero's chromocytometer, Malassez's hæmochrometer, and Heischl's hæmatometer, and he thinks that it is possible that this method of determination of dose can be applied to all the alterative forms of medication (iodine, alcalines, arsenical, etc.). In short, chromocytometry can be regarded as the exact measure of the indication of the use and utility of drugs that modify the activity of vital exchanges, because the true result (therapeutical) is the action that causes the augmentation of the blood globules, that is to say, the augmentation of the quantity of hæmoglobine.

The first important set question of this Congress was the Analgesic Antithermic Drugs, and M. Dujardin-Beaumetz, who reported the question, said it was important to fix the therapeutic indications of each of this group of medicines. This large and new series of bodies were taken from the aromatic section that had already furnished powerful antiseptics, then antithermics, and now analgesics. The number of these last seemed to increase daily, and it was lately a reproach that a drug was hardly known before a new one was introduced; but the eminent speaker did not think that this was just, as medicines that would take away pain could never become too numerous. He thought that to accomplish, according to the words of Hippocrates, a "diminution of pain by drugs was a divine work." What is important in this group is to fix the precise indications of each body and study the elective action of each one. The phenomenon of pain is such a complex one that it is easy to understand that a drug that calms migraine will not act against the pain produced by lesions of the nervous system; and, again, one that cures the

nervous pain will not act against rheumatic pain. There is, then, a considerable interest in not refusing the benefits of each of these drugs, but to seek to utilize the good effects of each. The physiological problem of these newer drugs is a very complex one, and requires much study. Many of them are antithermics, some act as antiferments and combat the *processus* itself of fermentation, others again act directly on the blood globules and cause a fall of temperature by diminishing the respiratory power of the blood. Other, again, act on the thermic centers in the medulla oblongata, and these last seem to have the strongest analgesic power. It is important to fix exactly on what part of the cerebro-spinal system they act upon, as the therapeutic application must differ accordingly. It is quite possible to modify any of these bodies, according to modern chemistry, and get the action of one or more of them combined. Dr. Dujardin-Beaumetz, with M. Bardet, think that they have established one important fact, that is, that the antiseptic effects of this series comes from the hydrated group (phenols, naphthols, etc.). The antithermic effects dominate in the starch group (acetanilide, kairine, thalline, etc.), and that the analgesic action is those bodies that have been generated in the amidon, or starch group, where an atom of hydrogen has been substituted to an atom of the radical fats, and above all, methyls, such as dimethyloxyquinizine, or antipyrin, and methylacetanilide, and acetphenetidine.

In regard to antithermic medication there was a difference of opinion, M. Masius, of Liege, thought that the present condemnation of these drugs in fevers was wrong and he thought that they gave good results in typhoid fever, and, indeed, that they allowed of an easy method of prognosis, if the fall of fever heat obtained by the drug was rapid and the freedom from pain was considerable under the use of the antithermic, it was certain that the prognosis was good and the patient would recover. Dr. Williams, of Boston, did not think that it was well to give these substances to cause a fall of fever heat in typhoid fever. He thought it was dangerous, as in the first stage the dose cannot be raised enough to do good, while in the later stages the drug only weakened the patient without any profit to him as it retarded convalescence. M. Desplats, of Lille, said that the antithermics were wrongly so called, they are *antipyretics*, as they act on *all* the elements that constitute fever, certainly they have no action on temperature in healthy people, and they should not, therefore, be called antithermics. Dr. Desplats, was highly in favor of this form of medication, and cited the cases of fever and headache, even convulsions and delirium, that he had caused to pass a comfortable night by the use of these drugs. In smallpox, for instance, in the last stages when the patient has 40° C. or more, and the eruption does not take place, while the headache and backache is intense, a gramme of antipyrin will make all these symptoms disappear, and keep the patient quiet until the eruption takes place. M. Stockvis and Dr. Semmola thought that the antithermics were dangerous in continuous fevers, and if they gave a sort of repose it was at the expense of a loss of strength and the after-effects were bad, so they did not advise their use in fever, while they thought that antipyrin, in particular, was of great value as a pain reliever. M. Semmola proposed the *use of powdered sulphur as a medical and surgical antiseptic.* He had been led to this view by seeing the action of sulphur as used by the farmers in agriculture. He gave flowers of sulphur in one-gramme doses, and increased it to two grammes, to be followed by plenty of drink. He found a complete tolerance for the sulphur, and as much as twenty grammes can be given in twenty-four hours. The intestinal antisepsia produced was remarkable, while the general state of the patients was much improved. Dr. Semmola ordered at the same time that the sheets of the patient be powdered with sulphur, and found that this sulphurous atmosphere had a good influence over the patients. He also proposed that surgeons make use of powdered sulphur in place of iodoform. M. Jorissenne said that *anal fissures* were kept up by the action of microbes, and that they could be cured by a pommade of corrosive sublimate, and most likely by other antiseptics. The ointment must be applied with the finger, passing it up the rectum about three centimetres.

Dr. C. Paul proposes the following as the best tooth powder:

℞.—Bicarbonate of soda . . . . . 2 parts.
Saccharine . . . . . 3 "—M.

He finds that it is a most powerful antiseptic against all the bacteria of the mouth.

SOME NEWER FRENCH PRESCRIPTIONS.

Guajacol is recommended in place of creasote, as being much less irritating.

℞.—Guajacol . . . 7 grammes, 50 centigrammes.
Tinct. cinchona . . . . 20 grammes.
Malaga wine . . . . . 1000 grammes.
M.—Each tablespoonful is 75 centigrammes and one to three of them is given after each meal.

It may be used also in rectal injection when the stomach is bad.

℞.—Guajacol . . . . . 2 grammes.
Sweet almond oil . . . . . 20 "
Gum arabic . . . . . 10 "
Aqua distill. . . . . 950 "
M.—This is enough for four injections.

Heimann gives phenacetin in doses of 0 grammes, 10 centigrammes to 0 grammes. Forty per day to children with whooping cough with great success.

For acne of the face M. Guilleton uses:

℞.—Iodochloride of mercury 0 grammes, 30 centigram.
Lard . . . . . 30 grammes.
M.—Sig. Use a little with prolonged friction. The reaction produced is very energetic.

Prof. Ball, who holds the mental chair at the Paris school, gives the following gurgative pill at his clinic of mental diseases:

℞.—Aloes (succotrine) . . . . . 2 grammes.
Resina jalap, scammony and calomel āā 1 gramme.
Ext. belladonna and hyosamus . āā 0.50 centigm.
Soap . . . . . 91. grammes.
M.—F. 100 pills. Sig. Three to five at night as needed.

THOMAS LINN, M.D.

EVOLUTION IN DISEASES OF THE NERVOUS SYSTEM.

RARELY does it happen in the meetings of medical societies to have a paper read so full of fresh thought and originality as the one by Dr. Hughlings-Jackson presented to the British Medical Association. So subtle are its arguments, so apt is its phraseology, and so thoroughly scientific is its philosophy that we could not let it pass unnoticed. Evolution as a doctrine grew naturally out of the efforts to group and classify an overwhelming mass of natural facts. In many respects pathology is much like zoology before the days of evolution; it is composed of a mass of isolated facts, a few, very few of which have been at times arrayed in a kind of classification. What medicine needs are broader generalizations and working hypotheses by means of which these facts can be better arranged and more closely studied in comparison with one another. In regard to the nervous diseases at least, Dr. Jackson thinks that we have such a working hypothesis in the theory of evolution.

Anstie, Ross, Ribot, Mortimer, Granville, Mercier, and Bland-Sutton, have all endeavored to apply the theory of evolution to normal and abnormal conditions of man's body; hence the subject is not a new one.

In the normal development of the nervous system evolution is always advancing from the most to the least organized, using the term organized in the sense of being fixed. Thus, the most highly organized nervous centers, those which preside over the simple functions of vitality, are common to all creatures alike, but as we proceed higher in the scale of animal life, we find the higher, more delicate, and less stable centers making their appearance. Now, if we regard the entire nervous system, even the undecided areas of the frontal lobes, as simply a sensori-motor apparatus, we can trace out the evolutionary development of the different centers in the different animals by their relative delicacy, subjection to the individual's control and stability. Coarse sensations and gross muscular movements are connected with nuclei developed in the evolutionary scale relatively lower than those which give rise to finer sensations and finer movements.

The highest cerebral centers are the least organized, although they are the most complex, while the lowest centers are the most organized. Evolution of normal structures is therefore from the most automatic or least modifiable to the least automatic or most modifiable. Disease or dissolution is simply the reversal of this process, and upon this principle many of the anomalous symptoms of mental and nervous diseases may be understood and classified.

It must be remembered that the nervous system by itself is a functional nothing; it is only something as representing parts of the body, and as we watch a progressing paralysis, whether of the motor or sensory apparatus, involving first the more delicate and voluntary movements and sensations, we recognize the fact that the lesion is gradually encroaching upon and overcoming first the higher and then the lower centers. If one study the symptoms of progressive nervous diseases, he will see that such is their onward course. In the action of the thermal apparatus in fevers, in insanity, in the dissolution of drunkenness, and even in the action of such poisons as alcohol, it

will be seen that the more delicate and voluntary processes go first. Even in epileptic fits, hemiplegic strokes, and aphasia the same law of evolutionary development is illustrated, but in a reversed direction. Confusion arises in studying these groups of symptoms from not clearly separating the positive from the relative results of the lesion. Destruction of nervous matter invariably means paralysis or some degree of it, and the various tremors, incoördinations, which mar the perfect picture of a nervous degeneration, are due to the activity of the remaining structures. This is a simple fact which must be clearly borne in mind. The tremor in a case of disseminated sclerosis is to be attributed to the loss of balance between all parts of the affected nervous center, and the singular ideas of insanity are the results of not the paralyzed centers, but the remaining healthy centers. With this mode of carefully studying the symptomatology of every case of nervous disease, the examiner will rarely fail to discover that the progression is always from the least highly organized or most voluntary or last acquired centers to those below them.

The question naturally suggests itself then whether diseases can be classified in any systematic order, according to this principle of evolution. Not positively until we know more positively the relative positions of the various nerve-centers in the evolutionary scale. However, we can make the attempt, and at the present time the evolution theory seems to offer the best principle of classification. For example: (1) Progressive muscular atrophy, (2) paralysis agitans, and (3) general paralysis are all homologous diseases. In the first, the lowest centers are cut off from the higher ones (middle and highest, which preserve their powers, as shown by the *more* complex and *most* complex movements of the hands being retained). The loss is only of the simplest movements (cerebral and cerebellar) represented in some of the lowest motor centers (anterior horns). In the second (hypothetical, however) the loss is of the *more* complex movements represented in the middle motor centers. There is retention of the *most* complex movements represented in the highest centers, and also of the simplest represented in some lowest. In the third there is loss of some of the *most* complex ("finest") movements represented in the highest motor centers and in those entering into the physical bases of tactual ideas and other mental states. There is retention of less complex (middle) and of simplest (lowest) movements.

Thus, the author has endeavored to show how the nervous diseases may be studied and arranged according to their evolutionary significance. It is unfortunate that our knowledge of many of the special diseases themselves should be so meager as to prevent our testing the principle throughout in all its details; but since it seems founded upon a logical basis (which must be if, indeed, the theory of evolution be logical and correct), it is worthy of the most careful consideration. Doubtless if it prove a substantial basis, neurology, as a positive science, will be more consistent and harmonious than it now is. For the credit of medicine, we hope that some such scientific basis of classification as herein proposed by Dr. Jackson may soon be discovered.

THE CARE OF THE CHILDREN.

NOW that the long vacation is over, and the schools are commencing their winter sessions, a word in behalf of the children will not be out of place. Statistics have shown that a scholar's life is the happiest, healthiest, and longest. In the exercise of the brain usually all the faculties are employed in a way that is rarely possible in other modes of life, and with a judicious care of the physical being, the balance between mind and body is so nicely maintained as to verify the truth of the old adage, *mens sana in corpore sano.* The conditions for the maintenance of health and happiness belong more abundantly to the scholar than anyone else. The wear and tear of a one-sided business life, in which all one's energies are bent towards the single purpose of self-support, will rarely allow the exhausted nature, however disposed it may be, to indulge in the more artistic and refining recreations of life. And, on the other hand, continual play, as indulged in by the growing infant, would be most unwholesome for the boy or girl with the rapidly-developing active brain.

Hence, a carefully managed school life, aside from its other advantages, is the best for the young. But how often are these advantages lost by badly-ventilated rooms, irregular and long hours, too strict discipline, deprivation of meals, lack of outdoor exercise, supernumerary tasks, and the many other evils that bring around with the coming spring of the year the delicate, bent forms and pale, flabby faces of the little ones.

We could wish that the vacation had been extended beyond the heated term of early September, as in many of the cities the public schools do not begin until near the end of the month. But this evil would not be a serious one if some of the others above mentioned were guarded against.

First and foremost of importance is the regulation of the classroom discipline. A certain amount of leniency must be admitted. To require children to sit hour after hour gazing in a certain direction, with backs straight, and, perhaps, in the midst of bad illumination, is both barbarous and unnecessary. The teacher should, as far as possible, learn the disposition and physical condition of the pupils, so that when necessary the calls of nature may be answered and yet the appropriate order maintained. Girls, for instance, are sometimes subject to weakness for which they must retire more frequently than is usual. To disregard such a condition might lead to life-long misery and ill heath. The home tasks should be made as short as possible, instead of the reverse, which seems to be the inclination of many teachers

nowadays. The younger the scholar the less the number of home tasks, is a very good general rule.

Mothers should see to it that their offspring receive the proper hygienic attention. Bathing, appropriate comfortable dressing, and plenty of nourishing, plain food, taken at regular intervals, are all objects that need merely be mentioned and yet that are most frequently forgotten.

Many suggestions could be made in regard to the children's school life, but most of them are so familiar as to be known to everyone. We merely want to call attention to the subject at this season of the year, and recommend to the family physician, who has his own interest and that of his patients in mind, to speak of it, and even during the winter to look after the welfare of the children, even though they be not sick. It will be appreciated by the family, particularly if any of the suggestions are new; and the health of society, both now and to come, will be better preserved.

PERFUMES AND OZONE.

OZONE may still be regarded as one of the unsolved mysteries of nature, though it has been devotedly investigated, within recent years, by certain chemists. Then, also, all sanitary authorities are in agreement upon the point that it is a natural purifier of the atmosphere of great power, attacking with particular energy azotized substances and other organic impurities. There is not, however, conclusive evidence at hand to show, as some writers contend, that it destroys by oxidation those fungi which are known to cause disease; and yet since it annihilates atmospheric substances that acts as carriers of disease-producing germs, it may become the indirect means of preventing, under certain conditions, the spread of contagious and infectious diseases. Its office is, therefore, a highly salutary one, and from a sanitary point of view cannot easily be over-estimated.

The natural sources of ozone is a subject of lively interest. That it can be prepared artificially in various ways is a well-known fact. A recent writer (*Shirley Dare*) in the Philadelphia *Press*, discoursing upon the subject of perfumes, states: "One of the most exquisite offices in nature is that performed by scents of flowers in purifying the air, and breathing ozone into it by their perfumes. Not all sweet-scented plants do this, or all pleasant odors. The distinction is marked between the sedative odors and the reviving ones. Lilies, jasmine, tuberose, orange flowers and acacia, in their natural form, borne on the winds and mixed with many thousand times their own volume of air, are pleasant, soothing to a healthy sense, though delicate nerves cannot enjoy them even in their garden freshness.

"Brought closer in clusters of blossoms their odor is narcotic, depressing, so that persons grow faint at smell of them, and yet more concentrated, their effect is stupefying and deadly. Well authenticated instances abound of persons sent into heavy slumber, as if drugged, by the odor of lilies or jasmine, and the scent of orange flowers is so depressing to the action of the heart that it is not safe for anyone with disease of that organ to inhale it any length of time. It is not at all imagination when nervous, susceptible persons complain of discomfort from the powerful scent of flowers or essences of any sort.

"The reviving scents arise from herbaceous plants largely, from the odor of the rose, mignonette, lavender, thyme and lemon verbena, balsamic rosemary, and, chief of all, the carnation family, including spicy stocks, wall flower and pinks."

The fact that the "scents of flowers" generate ozone was first discovered by Dr. J. M. Anders, of this city. According to the results of the experiments by this observer, all flowering plants, including scented foliage—pine and hemlock foliage to a marked degree—possess this important property. In his work on "House-plants as Sanitary Agents," Dr. Anders calls attention to this well-known fact that a great variety of emanations are given off by growing plants, "most of which are delightful to the sense of smell, whilst a small proportion only are repugnant or harmful." Concerning those plant odors which have injurious effects, he draws the following conclusions: "First, the lethal effects ascribed to plant odors by some of the ancient writers must be absolutely apocryphal. Secondly, highly scented flowers, such as the tuberose, magnolia, and certain lilies, have an injurious effect, and should in all cases be discarded, so also all plants having intensely disagreeable odors. Thirdly, those emitting milder odors—the rose, heliotrope, mignonette, for instance—which flowers occasionally produce unpleasant effects, should, whenever found to do so, be excluded, but such are not to be totally condemned, since the hygienic advantages attendant upon their presence are actually noteworthy."

Again, in view of the latest scientific researches, a few of the statements made by the writer in the *Press*, before quoted, are misleading and need to be modified. We restate them: "Not all sweet scented flowers do this or all pleasant odors" (*i. e.*, generate ozone). The distinction is marked between the sedative odors and the reviving ones."

As before stated, it seems to have been shown by actual experiment that all scents of plants generate this substance, some of these examinations, however, having the marked disadvantage of exercising unpleasant and even depressing effects, particularly upon the sick and invalid.

Dr. Waugh has been absent in the West for the past three weeks, during which time Dr. L. Harrison Mettler has had editorial charge of the journal. Our readers will be pleased to hear that Dr. Mettler will continue to participate in the editorial work of the journal.

Annotations.

MANAGEMENT OF INGROWING NAILS.

THIS very common trouble has long been unsuccessfully managed, because of erroneous designation. It is exceeding doubtful if the nail grows laterally at all; it is more probable that lateral mechanical pressure produces an abrasion, which lying in contact with the unyielding edge of the nail, produces a proliferation of tissue with resulting granulations. This is the true pathology of ingrowing nail. We are glad to discover that so able a surgeon as Dr. Fred. Lange shares this view. While he does not express it in words, his treatment by removing the affected fleshy parts, indicates it. Dr. Lange (Med. Monatschr., August, 1889, 403) applies bismuth and a few threads of antiseptic gauze, when it is possible to reach below the hidden nail-corner, after trimming the latter obliquely, to the ulcerated slit. A small pad of antiseptic cotton is pressed over the swollen parts by plaster, which must not, however, encircle the entire toe. In more pronounced cases, the toe being thoroughly disinfected by repeated baths, is rendered bloodless by the application of a drainage tube. A two per cent. sol. cocaine is injected near the root of the nail into the swollen flesh, other injections are made so as to anæsthetize the field of operation. The entire mass of flesh lying in contact with the nail border is fully excised, so that the latter lies free in a wound whose lower border is in contact with the volar edge of the great toe. This is not too much, because the parts are very soon restored. The nail itself is not touched, but any ulcerated remainder of the nail bed is thoroughly curetted, cleansed with 1 to 1000 sublimate solution and covered with iodoform ether. A few threads of iodoform gauze are placed under the nail border. The free bleeding, which sometimes ensues, may require ligation of some dilated arteries. The wound is covered by a piece of oiled silk or rubber tissue, and dressed with an iodoform bandage. This dressing may remain four to six days and need not be removed even if it be saturated with blood. When granulations appear they are dressed with a salve and the nail is kept trimmed. Dr. Lange resorts to no other operation, having found that the most affective and least troublesome. A few weeks are required, but in the second week the patient may resume his occupation. The wound must now be covered with a suitable plaster.

We have pursued a similar treatment successfully, having discarded the barbarous nailsplitting and extracting twenty years ago.

CHLORALANOID, the new hypnotic, is favorably reported on from Prof. Strumpell's clinic. Although Drs. Hagan and Huefler did not expect much from it, their results have been so encouraging and indisputable as to induce them to recommend it as one of the most reliable hypnotics. Chloralanoid is a colorless crystal, of bitter taste, and may be administered in wafers or in wine; the dose is thirty to forty-five grains. Sleep is produced in half an hour and lasts till morning usually, without disturbing the functions. Its effect is more pronounced than that of chloral and the dose is a little less. It has no specific effect upon pain or other symptoms, except in cardiac asthma, in which it relieved distress and improved the pulse. Among twenty-eight cases of organic disease of the heart, lungs and kidneys, this remedy failed in only two as an hypnotic; further investigations are necessary in purely nervous affections.—*Wiener Med. Blätter.*

Letters to the Editor.

THE ELIXIR.

I HAVE noted the reports of the experiments of various physicians with the "Brown-Séquard Elixir," and am constrained to a few remarks. There seems to be a prevailing notion from the particular material constituting the "Elixir" that it has particular power in rejuvenating the sexual capability of the aged or those from whom it has departed, whether by reason of age or other cause. I notice, however, that some American experimenters seem to be depending more upon an exhibition of a general tonic effect, whether upon the aged or those debilitated by disease.

If it is only the generative element which is derived from the testicles of the various animals used (and it seems to me there is nothing else), then the testicles of the lamb can furnish only an imperfect or unelaborated element, to use which appears to me illogical.

I am not prepared to decry a possible (?) valuable result from these experimental injections, but would suggest that if it is desired to derive materials from animals of known high propagating powers particularly salacious natures, or it would be better to obtain the seminal fluid direct from the living animal, and I should think a mature "billy" goat, a "Darby" ram, or a jack, could best furnish this, and with but slight persuasion; this would be material of a quality which, if there should be a possible virtue as an aphrodisiac, would appear without fail. The testicles of the rooster would also furnish material particularly choice.

The animals above noted could furnish the juice—the perfected material—without destruction of their lives or power to further procreate; the rooster would have to be caponized or killed.

If in the making of these "Elixir" injections the object is only that of general stimulation, or better yet, the improvement and rejuvenation or strengthening of functions which are failing, as the muscular force, mental or nervous energy, or the secretions of the glandular system, why might not that effect be equally well produced by the use of the same amount of beef similarly prepared as the "Elixir," and used in the same manner? It is worthy of trial, and the patient need not be informed of the substitute, so that the results may be observed without prejudice.

While in some respects the use of the "Brown-Séquard Elixir" seems to be unnatural in the expectation of rejuvenating results, and exceedingly absurd, yet I do not feel prepared to ridicule the efforts

of many respectable men, who, though they may be sceptical, desire to "hold fast to that which is good," by seeking the good. Bergeon's rectal treatment of phthisis by the use of sulphuretted hydrogen was no less strange than this latest novelty for the relief of suffering and failing humanity. Careful experiment showed its inefficacy and the principle to be fallacious, and the same I think will appear in the "Brown-Séquard Elixir." Let the experiments continue if they do no harm, until a correct conclusion can be arrived at. Has Brown-Séquard used his own Elixir, or is he another Count Waldeck?

A. C. W. BEECHER, M.D.

PHILADELPHIA.

CONCEALED HEMORRHAGE AT THE FIFTH MONTH OF PREGNANCY.

ALLOW me to report, through the columns of your weekly, a case that came under my notice and treatment some three years since in the person of a married lady, at that time about twenty-seven years old, whom I had previously delivered of two children at full term, there being sixteen months between births.

About the first of April, 1886, I was informed by her husband that she was again pregnant; and some time in July following I was notified that she was not doing well, and that she had become quite weak within the past few days, and that her abdomen had been rapidly enlarging.

Within two weeks from this time she had become as large as at full term, though only four and a half or five months pregnant. I did not visit her, as I was not requested to do so, but prescribed a mild laxative and tonic. At the end of a week from the time of prescribing I was sent for in haste, and upon my arrival at the bedside found a four and a half or five months' fetus lying in bed, still attached to the mother by a very short and weak cord. As the child was dead, and not viable, had it been living, I clipped the cord without tying, and proceeded to make further examination. The bed was perfectly dry; not a drop of blood or water that I could discover had escaped, the lady telling me that she had not felt the least flow of any kind. Her abdomen was not in the least reduced in size, but was considerably larger than she had ever been at full term.

Upon a digital examination, I found the entrance to the cavity of the womb securely closed by a somewhat fluctuating membrane, which was almost as tight and unyielding as the head of a drum.

With my index finger I made strong pressure against the obstruction, when it suddenly ruptured with a gurgling thud and a stream of dark blood gushed from the parts. The flow was so large and rapid that it soon overflowed the bed and ran down upon the floor, which was not carpeted, and formed a pool at least a yard and a half long and more than half as wide. As the flow continued the abdomen gradually shrank so that when the current ceased it had gone down to its normal size. I then removed the after-birth which still hung in the mouth of the womb.

Now here was a dangerous concealed hemorrhage of some three weeks standing, during which time the woman had lost at least a gallon, or perhaps a gallon and a half of blood, without a single drop having reached the external world, to give a hint as to what was going on in the cavity of the womb.

I could only discover a few shreds of membrane, therefore conclude that the sac covering the embryo was but a mere envelope sufficiently large to hold the fetus, but not large enough to hold a discoverable amount of water.

The above account is strictly correct, and I have endeavored to make it as plain as possible. If any of the brethren can give a better explanation of the case, than I have hinted at, and thereby clear up the matter so as to make it plain to the ordinary professional mind, I shall be extremely glad to hear from them.

J. A. WARD, M.D.

TROY, MO.

ANTIFEBRIN.

IN reply to Dr. Endicott in reference to antifebrin, where he claims our dose was too large and temperature too low, I hold that a persistent temperature of 102° destroys the tissues of the body, and in the case cited it ranged as high as 103°, so the reader may judge in regard to the propriety of antipyretic treatment. As to dose and effects authorities differ. He would have it repeated within three or four hours; yet we are informed by others that its effects remain six hours; in which case would not our Doctor commit the same mistake as Dr. Penny, who, you claim, repeats the dose too often?

Book Reviews.

A SYSTEM OF OBSTETRICS BY AMERICAN AUTHORS. Edited by BARTON COOKE HIRST, M.D. Volume II. Philadelphia: Lea Brothers & Co., price $6.

This volume of the American System of Obstetrics is a fitting close to a work of such high merit as was promised in the prospectus published some time since, and which was more than realized with the appearance of the introductory volumes. Dr. Hirst having evidently exerted every effort to give to the undertaking that completeness to which it was entitled, we feel jnstified in saying that he has succeeded even beyond the most sanguine expectation, and that he deserves the congratulations and thanks of the profession at large for the valuable addition he has made to obstetrical literature. We can heartily commend the system to our readdrs as a worthy exposition of the branch of obstetrics.

The subject-matter of this final volume may be conveniently separated into three portions. In the first of these the interesting subject of dystocia in all of its various phases and complications is ably discussed by such well-known authorities as Parvin, Davis, Cameron and Harris. Laceration of the cervix and perineum, uterine rupture, inversion of the uterus, placenta prævia, post-partum hemorrhage, puerperal eclampsia, the premature induction of labor, operative obstetrics including the use of the

forceps, version, embryotomy, the Cæsarean operation, symphysiotomy, laparo-elytrotomy and laparo-cystectomy are all included here, and are thoroughly discussed in their every aspect.

Two or three points worthy of special mention attract our notice as we glance over the pages. Thus Prof. Parvin, in speaking of inversion of the uterus, rejects two of the symptoms which are classed in most obstetrical works as characteristics of this grave accident and as valuable aids in its diagnosis, namely, the presence of intermittent contractions and of undue sensitiveness of the inverted organ. He believes that these may prove doubtful or even deceptive in most cases. He also denounces the practice of confining the knees after perineorraphy or perineoplasty as an "unnecessary cruelty."

Dr. Cameron, in his article on the "Induction of Premature Labor," would impress upon the people the great practical importance of prophylaxis in obstetric matters. He says: "If patients would only place themselves under the charge of their medical attendants early in the course of their pregnancy, much suffering would be prevented, many lives saved, and dystocia and eclampsia robbed of half their terrors." We feel that the distinguished writer but expresses the sentiment of every thoughtful practitioner in thus pressing upon the people prophylactic treatment during gestation. Too often is the obstetrician called in to assist in a difficult or impossible labor with its attendant evils, all of which might have been avoided by proper medical supervision during early pregnancy.

The second portion of the volume is devoted to a comprehensive study of the diseases to which the puerperal woman is subject. Puerperal fever, that bugbear of obstetrical practice which, like the sword of Damocles, hangs over the head of the obstetrician, threatening ruin and disaster, is discussed by Dr. Garrigues, of New York, in a masterly manner. Its prevention and treatment as it appears in hospital and private practice are both considered, and especially is the use of some antiseptic agent, preferably a solution of the bichloride of mercury, urged in every case, even at the expense of a little additional time and trouble to the practitioner. Mastitis and other affections of the breasts and nipples, subinvolution, retention of the placenta and membranes, displacements of the uterus, puerperal hæmatoma, and other complications of the puerperal state are considered by Drs. Garrigues and Hirst, while Dr. Lloyd writes upon puerperal insanity and the other neuroses of the child-bearing woman.

The book closes with a careful study of the management and of the diseases of the newborn infant, including all surgical affections of the child, together with a review of the congenital anomalies of the eye, the latter by Dr. G. E. De Schweinitz, of this city.

THE PHYSICIAN HIMSELF AND THINGS THAT CONCERN HIS REPUTATION AND SUCCESS. By D. W. CATHELL, M.D. Ninth Edition, Revised and Enlarged, pp. 298. Price, $2.00, net. Philadelphia: F. A. Davis. 1889.

By reason of the nature of his calling, a physician needs to exercise more of that peculiar quality commonly known as tact, than anybody else. However learned or skillful he may be, unless he is able to win the confidence of the patients, his ability will fall short of its highest possibilities. In acquiring the history and symptoms of a case he will often have to exercise the subtlest ingenuity. But success in life is not always dependent upon knowledge and skill, more frequently it is the result of a certain bearing of manner, of influential backing or judicious self-assertiveness, and often it is a most difficult problem to know just where to draw the line between men; braggadocio of word and manner and a legitimate display of one's best abilities. As success is the aim of every human being, the physician is justified in adopting every means in his power to attain that end. With a remarkable degree of shrewdness and deep wisdom Dr. Cathell has shown how best to attain the coveted success. The book will be especially valuable to the young practitioner who now a days has not the same advantages of that information acquired by close contact with a preceptor, as belonged to the earlier days of apprenticeship. The hints here presented in regard to such simple matters as dress, education, manners, system, office furnishings, methods of approaching the sick, etc., are of inestimable value. Being a physician himself, the author knows from experience the trial, hopes and successes of the ambitious young doctor; warns him as a friend against discouragements and points him to the success that results from industry, common sense and well-preserved honor, recommending him especially as a man and as a physician, always, and above all else, to keep whatever is honest, whatever is true, whatever is just, and whatever is pure, foremost in mind and to be governed by it.

TRANSACTIONS OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA. Third Series. Volume, the Tenth. Illustrated. Pp. 456. Printed for the College. 1888.

According to the last report the college has a membership of 255 fellows, resident and non-resident, forty-one associate fellows, and six corresponding members. The present volume of Transactions is issued in the usual style, and is particularly rich in addresses and scientific papers. Among the former, worthy of special mention, is the Biographical Sketch of Dr. Casper Morris, by Dr. J. Chester Morris; among the latter are the papers upon our Maritime Quarantine, being the report of a special committee, and also upon Membranous Enteritis, by W. A. Edwards, M.D.; Pneumonia, by Henry Hartshorne, M.D.; Friedreichs Ataxia, by J. P. C. Griffith, M.D.; The Walk and Some of its Phases in Disease, by F. X. Dercum, M.D., and Arteries and Veins in Bright's Kidney Disease, by Arthur V. Meigs, M.D. The illustrations and typography are admirably executed.

The *Popular Science Monthly*, for September is quite up to the usual excellence. The "Study from Life," by Olive Thorne Miller, is a chatty description of the queer antics of a pet lemur. "Recent Economic Changes," by Hon. David A. Wills, is a selection from the advanced sheets of this author's collected assays which recently appeared in the

monthly, and one now to be issued in book form by Appleton & Co. "The Surface Tension of Liquids," is an article by W. H. Larrabee, well illustrated, and offering some simple and highly instructive experiments. Prof. Huxley writes upon "The Value of Witness to the Miraculous." "Museums of Household Products," is a translation of a very suggestive paper by Prof. Vischow. Economic science is again represented by the second part of Dr. Oswald's paper "The Wastes of Modern Civilization," and Huntington Smith's "Ethical View of Protection." "Some Modern Aspects of Geology," is part of an address delivered at the commencement exercises of the Worcester Polytechnic Institute by Prof. G. H. Williams. One of the most interesting of all the articles is "Animal Life in the Gulf Stream," by Ralph S. Tarr. The illustrations are capital. "Origin of the Rights of Property," by H. J. Philpatt; "Arctic Ice and its Navigation," by A. A. Ackerman, and "A Corner of the Dutch East Indies," by Captain Sangen, are the three articles preceding the biographical sketch, with portrait, of Joseph Lovering.

Notes on the Electro-magnet in Ophthalmology with a Report of Nine Cases. By Wm. Ellery Briggs, M.D., Reprint from the *Occidental Medical Times*, August, 1889. Sacramento, Cal.

The Medical Digest.

THE following hints from Lassar's skin clinic are of practical value; we have tested them in eczema. Instead of fats porous pastes are used, made of the purest vaseline with oxide of zinc and starch, rubbed slowly together. These may be readily mixed with most remedies in use; they dry quickly and may be converted into permanent dressings by absorbent cotton, and this gauze be changed when saturated. On the face and other parts not accessible to bandages, ample powdering upon the paste-covered skin will afford a smooth and dry covering, which is easily removed by small oiled rags.

In *eczema of all kinds* the paste treatment offers great advantage over ointments. Lassar's usual formula is:

℞.—Acid. salicyl. 2
Vaselin. flav. 50
Zinc. oxid.,
Amyli . . . . . āā 25

In *parasitic troubles* (herpes tonsurans, etc.) sulphur precipit., 10 per cent., sozojodol, 5 to 10 per cent., or resorcin, 5 to 10 per cent., may be added. On hairy parts vaseline salves are better.

In ordinary *dry or moist eczema of the scalp in children* the head should be gently washed with chamomile and soap, and then the following applied:

℞.—Acid. salicyl. 1
Tr. benzoin 2
Vaselin. flav., ... ad 60

In *intertrigo*, penciling with a 3 per cent. solution of nitrate of silver should precede the salve.

For *frost-bites:*

℞.—Acid. carbol. 0.5
Vaselin.,
Ung. plumb. . . . . āā 10
Ol. olivæ 5
Ol. lavand., ... gtt. 10
M.—Ft.

For *calming inflamed skin:*

℞.—Zinc. oxid. 25
Ol. amygd. . . . . q. s.
M.—Ft. Pastu mollis.

In *acute eczema*, Lassar warns against watery solutions and compresses.

For *pruritus:*

℞.—Acid. carbol. 1
Menthol 1.5
Talci . . . . . ad 50
M.—Menthol powder.

℞.—Menthol 2.1
Bals. peruv. 5
Ung. Wilsonii,
Lanolini . . . . . āā 20
(With care on face.)

For *pruritus ani*, sitz baths of tar-water and penciling with 2 to 3 per cent. nitrate of silver solution, also carbolized lead salve.

For *acne vulgaris and rosacea*, a peel paste is used.

℞.—B-Naphthol 10
Vaselin. flav.,
Sap. virid. . . . . āā 20
Sulf. præcip. 50

To be applied by the physician and to remain fifteen to sixty minutes; then gently removed and replaced by powder or white paste. This is repeated after peeled surface is healed; or the following may remain over night:

℞.—Resorcin 2.5–5.0
Zinci oxid.,
Amyl. . . . . āā 5
Vaselin. flav. 12.5
M.—Ft. Paste.

—*Int. Klin. Rundschau.*

"In no disease, except, perhaps, in pneumonia, have I seen more fatal results from exertion on the part of the sick, or from anything more than a sudden change of posture, than in diphtheria. Unless absolute rest be enforced, neither physician nor nurse have done their duty."—*Dr. A. Jacobi.*

"To keep a young girl, during her first efforts of sexual development, seated upright on a music stool, with her back unsupported, drumming vigorously at a piano for several hours, can only be detrimental."
—*Lawson Tait.*

M. Van den Corput has often noticed that in persons subjected to antiseptic medication, the sexual appetite is considerably diminished and he raises the question in regard to the action of these medicaments upon the spermatozoid whether it is the same as upon the microörganisms.—*Bulletin Gen. de Therap.* August 15.

M. Bucquoy, reported to the International Congress of Therap. Mat. Med. and Pharm. held at Paris that the purpose of the heart tonics is to relieve its action rather than to combat its lesions and that alongside of digitalis, which of itself answers every requirement, we may place other new drugs, caffeine, convallaria, Adonis vernalis, strophanthus, scilla and again Antiaris toxicaria, black hellebore, erythrophlaeum, nerium oleander, which have not yet entered into practical use.—*Bulletin Gen. de Therap.*

In the last number of the *Practitioner*, Dr. Donald Macalister, following the hints made twelve years ago by Dr. Pye-Smith, in regard to clearness and conciseness, so much desired in medical nomenclature, offers a couple of suggestions upon the same principle.

I. Tubercular, Tuberculous: Tubercular meningitis is evidently intended to be something different from tubercular leprosy. He would suggest that tubercular be used only to denote a morphological appearance, while tuberculous be employed only as the adjective corresponding with the noun tuberculous. Tubercular would imply a condition in which small nodes or nodules were apparent, as in tubercular syphilides, tubercular acne, leprosy etc. Tuberculous he would confine to a condition of tuberculosis, as tuberculous phthisis, tuberculous meningitis, tuberculous glands.

II. Diphtheritic, Diphtherial! The latter should refer to the specific disease diphtheria, while the former should be reserved for the variety of inflammation whether induced by the poison of diphtheria or not.

Pathological Inferiority of the Left Side of the Human Body.—When a unilateral lesion attacks any of the double organs of the human body, the left organ is more frequently affected than the right. Thus, obliterating arteritis attacks the left Sylvian artery, tuberculous infiltration occurs in the left apex, pneumonia in the left lung; calculous nephritis or cyst of the kidney, attacks the left kidney; ovaritis and ovarian hyperæsthesia are observed in the left ovary; orchitis affects the left testicle, etc. M. Henry Duchenne tries to explain this fact by the greater activity of the right side of the body and the relative passive condition of the left side, which contains the heart. The mechanical activity of the right side determines nutritive activity. The mechanical passivity of the left side produces a kind of physiological mealiness, a pathological predisposition. Dr. Duchenne considers that the law of atavism may also explain the physiological inferiority of the left side of the body, for in ancient times, when hand-to-hand fights were always occurring, the activity of the right side of the body was constantly called into play.
—*Medical Record.*

The Diagnostic Tampon and its Value in the Recognition of Chronic Endometritis.—B. S. Schultze (*Centralbl. für Gyn.*, March 11, 1889). In 1880 Schultze described a method which he had been employing for several years as furnishing a means for the early diagnosis of endometritis. He now reaffirms all that he then said of the value of his method, and expresses much surprise that it has not attracted a greater amount of attention. The diagnostic tampon is made of absorbent cotton soaked in a 20–25 per cent. solution of tannin in glycerin. This, after careful cleansing of the vagina, is pressed firmly against the cervix so as to fully cover the os and portio vaginalis. The glycerin solution absorbs water from the surrounding tissues and allows it to escape, together with the watery part of the secretions, the remainder of which is arrested by the cotton. After twenty four or forty-eight hours the tampon is removed, whereupon, if the uterus be healthy, a lump of vitreous cervical mucus is found. If, on the other hand, any portion of the mucous membrane above the tampon is secreting pus, the secretion will be found on the tampon. It is not the quantity and watery character of the secretion that proves the presence of endometritis, but the pus therein contained. The quantity of the secretion is often so moderate that patients do not complain of it, and, indeed, if the cervix and vagina are not affected a very considerable degree of endometritis may occasion so small a discharge that patients assure their physician in good faith that there is none.

Schultze claims that too much stress is laid upon abnormal discharge of blood as the diagnostic feature of endometritis, and that there is a much larger class of cases in which hemorrhage has not appeared or does not tend to appear, and that these very cases of beginning endometritis are easily recognized by means of his tampon.

DR. THOMAS G. ASHTON, Resident Physician at the insane department of Blockley Almshouse, has tendered his resignation.

DR. J. SOLIS-COHEN, of Philadelphia, was recently elected Honorary Fellow of the British Laryngological and Rhinological Association.

A PHILADELPHIA druggist advertises in his window that tablets made of the genuine Brown-Séquard elixir can be obtained inside. That no doubt can linger in the mind of any one respecting their genuineness, he has three live rabbits frisking in the same window.

THE Camden Board of Health has decided to abandon until next spring the project of building a garbage crematory.

ACCORDING to Dr. Cornet, tuberculosis is nine times more frequent among nurses than among any other class of persons.

DR. HENRY C. FITHIAN, of Port Norris, N. J., a graduate of the University of Pennsylvania in 1877, shot himself through the heart.

FIVE persons, taken sick at a picnic in Fairmount Park, are supposed to have been poisoned by eating canned corned beef.

JOSEPH T. MONTGOMERY, a Wilmington jeweler, is suffering from blood-poisoning, the result of an injection of "elixir of life."

DIPHTHERIA has broken out in South Bethlehem, and the authorities have taken every precaution to prevent the spread of the disease.

FIFTEEN thrashers were poisoned near Tiffin, Ohio, by eating cheese. All were made violently sick, and it is feared some of them will not recover.

RECENTLY the Board of Health was again without a quorum, only one member, Dr. Keyser, having put in an appearance for the usual noonday meeting.

THE services of a competent young American physician are desired by Americans living in Venice, Italy. This is an excellent opening for some one.

DR. LOOMIS, whose report upon the Brown-Séquard elixir appeared in our last number, is said to have concluded that no real benefit is derived from its use.

THE Board of Health refuses to permit the children of lazaretto employés to leave that institution daily to attend school, as it would be dangerous to public health.

AN epidemic of typhoid fever is prevailing at Ashland. The people are much alarmed, and the authorities have urged that strict sanitary precautions be observed.

DR. WALTER MCCLURG, United States Navy, has been appointed chief of the Bureau of Medicine and Surgery in the Surgeon-General's Department at Washington, D. C.

DR. J. H. HAZEN, a veteran of the War of 1812, who was wounded while serving under Commodore Perry, on the Niagara, died at Marshall, Ill., last Saturday, aged 91 years.

DR. F. W. FERRIE, a prominent physician of Indianapolis, died suddenly on Saturday, in his office, and opinion is divided as to whether he killed himself, was murdered or died from disease.

A BOSTON doctor says we must quit chewing wooden toothpicks, as the small particles cause gastric ulcer. We have found that small ulcers of the mouth are caused by this habit.

THE deaths in Philadelphia from cholera infantum last week dropped to 22; while 53 citizens succumbed to consumption, 6 to diphtheria, 4 to croup, 21 to typhoid, and 9 to other septic affections.

Ink and rust stains are removed easily by a solution containing ten parts each of tartaric acid, alum, and distilled water. The solution has the trade name of "encrivoir."—*Pharm. Ztg.*

The suggestion has been made to cremate the bodies exhumed from the graveyard at Eleventh and Carpenter Streets, by the excavations made for the sewer. The cholera dead were buried here in 1832.

Cremation in Berlin.—The police authorities of Berlin have recently refused the request of the Cremation Society to be allowed to cremate the bodies of all those who had signified their wish to be so disposed of.

The Vermont Microscopical Association has offered a prize of $250 for the discovery of a new disease germ. Information can be obtained of C. Smith Boyton, M.D., Secretary of the Association, Burlington, Vermont.

Progress of Medical Education.—The Iowa State Board of Health has decided that Iowa Medical Colleges after 1891 must give a four years course if they desire their graduates to be admitted to practice within the borders of the Commonwealth.

—*The Medical Age.*

As a general rule, a throbbing headache, with tenderness and soreness of the scalp, can best be relieved by hot applications. Whereas, where the head feels full and "bursting," if cold be applied to the head and the heat to the neck and spine, the effect is most agreeable.

The Cesarian operation was successfully performed on a colored woman in Christiana, last week, by Drs. J. J. Black and R. R. Tybout, of New Castle, and B. B. Peters and F. L. Springer, of Christiana. The child is a male, weighing eight pounds, and with it was extracted an eight-pound tumor.

At the very outset of the school season Medical Inspector Taylor has been compelled to report no less than nineteen public school buildings as nuisances and prejudicial to health. This, it need scarcely be said, is a shame and reproach to the community. A reform in the treatment of the local school buildings appears to be urgently necessary.—*Record.*

Dr. G. H. M. Rowe, Superintendent of the Boston City Hospital, has just returned from a vacation in Europe, where he visited many hospitals. He says: "Of all the hospitals that I visited I don't know of one that can compare with our Boston City Hospital, the Massachusetts General or the Johns Hopkins Hospitals."

In France, when a patient is under chloroform, on the slightest symptom appearing of failure of the heart, they turn him nearly upside down—that is, with his head downward and his heels in the air. This, they say, always restores him; and such is their faith in the efficacy of this method that the operating tables in the Paris hospitals are made so that in an instant they can be elevated with one end in the air, so as to bring the patient into a position resembling that of standing on his head.—*Record.*

As the days shorten and the nights grow cooler the malarial season tightens its grip upon the patient but helpless public. Damp air, impure water and unripened fruit are the agents which at this time of the year furnish doctors and undertakers with so much new business. Fruits are especially dangerous this year, the cool weather of summer having prevented them from ripening properly.

Dr. C. S. Bradfute, one of the resident physicians of the Pennsylvania Hospital, has tendered his resignation, to take effect on October 1, to accept the position of Demonstrator of Experimental Therapeutics at Jefferson Medical College. Dr. Westcott, who is the senior Resident Physician at the Hospital, will sever his connection with that institution in October, and will be succeeded by Dr. Joseph Leidy, Jr.

Cheap Medical Services.—A medical association has been formed in this city which advertises to furnish medical attendance to its subscribers for forty cents a month, and that all prescriptions for its subscribers will be filled by the leading pharmacists of the city for twenty cents for each prescription. In all probability the services and medicines are not even worth that.—*New York Medical Record.*

Strychnine in snake-bite acts with the unerring certainty and precision of a chemical test. Purely physiological in action, it neutralizes the effects of the snake-poison, and if pushed beyond the amount needed to neutralize the snake-poison, would itself act as a poison. Its poisonous effects, on the other hand, could be combatted by injections of snake-poison, could the latter be at hand in an emergency of poisoning by strychnine.

—Dr. A. Mueller in Australian *Medical Gazette.*

The Board of Health has ordered a house to house inspection in the Seventeenth, Eighteenth and Nineteenth wards, where typhoid fever has prevailed with unusual violence for several months past. The use of Delaware River water for drinking purposes is popularly supposed to be the cause of this outbreak, but the health authorities have determined to examine the drainage of all the houses in the afflicted neighborhood, note the condition of the cellars and alleys, and all other matters that may affect the health of the residents.—*Record.*

We, the undersigned, do hereby give notice, that according to the resolution passed at the Washington meeting, September 9, 1887, the Tenth International Medical Congress will be held in Berlin.

The Congress will be opened on the fourth and closed on the ninth day of August, 1890.

Detailed information as to the order of proceedings will be issued after the meeting of the delegates of the German Medical Faculties and Medical Societies at Heidelberg on September 17, in the current year.

Meanwhile, we should feel sincerely obliged, if you would kindly make this communication known among your medical circles, and add in the same time our cordial invitation to the Congress.

von Bergmann.
Virchow.
Waldeyer.

Dr. Lee has returned to his post of duty, and declares that the work of the State Board of Health must speedily come to an end unless more money is forthcoming. He is anxious to have a special session of the Legislature called, as he believes that there are hundreds of bodies that have not yet been exhumed, and that a serious epidemic may result if the Board of Health should relax its vigilance towards putting the locality in a thoroughly good sanitary condition.—*Record.*

Dr. Brown-Séquard.—The name of Dr. Brown-Séquard having lately been brought before the public eye more frequently than heretofore, considerable curiosity has been expressed as to his nativity. To satisfy this very natural desire, we will state that the doctor was born in 1818 in the island of Mauritius, where his father, Edward Brown, a native of Philadelphia, and previously master of a merchant vessel, was engaged in business. His mother was a French woman named Séquard, who lived on the island. All of young Brown's preliminary studies were made in Mauritius, and it was not until he had reached the age of twenty that he went to Paris to complete his medical course and take his degree. The language of his family and his youth is French, and he speaks it better than English, although in writing he has an equal command of either tongue. He has been married three times—first, to a Miss Fletcher, of Boston; secondly, to a Miss Carlisle, of Cincinnati; and his third wife, who is still living, is an English woman, the widow of an Irish engraver named Doherty.—*American Analyst.*

Mayor Fitler is a firm believer in the healthfulness of Schuylkill water, and has sent samples of the water to Germany for analysis by the most noted scientists there. He further proposes that a novel experiment shall be made with the disease germs which are said to abound in Schuylkill water. If these germs are deadly, the Mayor believes that they will affect the health of animals, and he has directed the German professors to inoculate rabbits and such other animals as they deem proper with the Schuylkill water germs and report the result to him.—*Record.*

To Contributors and Correspondents.

All articles to be published under the head of original matter must be contributed to this journal only to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer upon us a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 20, 1889, to August 26, 1889.

Tremaine, William S., Major and Surgeon (now on sick leave of absence at Buffalo, N. Y.). Will, by direction of the acting Secretary of War, report in person to the Commanding General, Department of the Missouri, for assignment to temporary duty at the post of Fort Leavenworth, Kansas. Par. 4, S. O. 198, A. G. O., August 27, 1889. Headquarters of the Army, Adjutant-General's office, Washington.

Porter, Joseph Y., Captain and Assistant-Surgeon. Resignation has been accepted by the President to take effect August 29, 1889. Par. 11, S. O. 200, Headquarters of the Army, A. G. O., August 29, 1889.

Matthews, Washington, Captain and Assistant-Surgeon. Promoted to be Surgeon with rank of Major, July 10, 1889, vice Town.

Ewing, Charles B., Assistant-Surgeon. Promoted to be Assistant-Surgeon with rank of Captain, July 5, 1889, after five years service, in accordance with Act of June 23, 1874.

McCaw, Walter D., Assistant-Surgeon. Promoted to be Assistant-Surgeon with rank of Captain, August 20, 1889, after five years service, in accordance with Act of June 23, 1874.

Bomister, W. B., First Lieutenant and Assistant-Surgeon. Granted leave of absence for fifteen days. Par. 2, S. O. 82, Headquarters Department of Arizona. Los Angeles, Cal., August 23. 1889.

Medical Index.

We purpose in this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Acne, treatment of, Fox. Med. Standard, August, 1889.

Alkalimetrische Untersuchungen des Blutes unter Normalen und Pathologischen Zuständen, Peiper. Archiv für Pathologische Anatomie und Physiologie und für Klinische Medicin, 1889, Heft. 3.

Antithermics, antipyretics, cardiac and cerebral sedatives, Akins. Western Med. Reporter, August, 1889.

Anatomical appearances, the, resulting from poisoning by arsenic, Draper. Boston Med. and Surg. Jour., August, 1889.

Croupous pneumonia, the treatment of, Kermer. Amer. Practitioner and News, August 17, 1889.

Die Suggestions, Therapei und die Angeblichen Gefahren bei Auwendung derselten. Internationale klinische Rundschau, 4 August, 1889.

Colon, flushing of the, Etheridge. Western Med. Reporter, August, 1889.

Ein Fall von Akromegalie, Aug. Bier. Deutsche Medizinal-Zeitung, 22 August, 1889.

Ein Fall von Angeforenem Tehlen der Zäpfcheus, Patozet. *Ibid.*

Eine neue Methode zum Färben der Miksoorganism im beson-deren ihrer Winperhaare und Geisselu, Loeffler. Centralblatt für Bakteriologie und Parisitenkunde, 18 August, 1889.

Electricity, the therapeutic uses of, Shoemaker. Jour. Amer. Med. Association, August 17, 1889.

Evolution, footprints in, Foy. Med. Press and Circular, August 7, 1889.

Facial erysipelas and erythema on the one hand, and intranasal pressure on the other, Major. N. Y. Med. Jour., August 10, 1889.

Fatal aural cases, Atkin. Med. Press and Circular, August 7, 1889.

Histologische Studien über Keratohyalin und Pigment, Mertschting. Archiv. für Pathologische Anatomie und Physiologie und für Klinische Medicin, 1889, Heft. 3.

Gangrenous hernia. on surgical treatment of, Richardsen. Boston Med. and Surg. Jour., August 15, 1889.

Hochgradige Ichthysis, im Säugungsalter, Rona. Archiv für Dermatol. und Syph., 1889, 3 Heft.

Insanity, proceeding from the colon, Moyer. Western Med. Reporter, August, 1889.

Klinische Terminologie, Roth. Deutsche Medizinal-Zeitung, 22 August, 1889.

Neurosis from ovarian diseases, Dana. Med. Standard, August, 1889.

Pathology, the, of hemoptysis from chronic pulmonary disease, Garland. Med. News, August 17, 1889.

Penis, case of amputation of the, for epithelioma, Armsby. Med. Press and Circular, August 7, 1889.

Poisoning, a case of, from canned Lobster, Staple. Hospital Gazette, August 10, 1889.

Pulmonary phthisis, the more recent treatment of, Canfield. Maryland Med. Jour., August, 1889.

Puerperal pyæmia, Coles. St. Louis Med. and Surg. Jour., August, 1889.

Sarcoma of the thyroid glands, a case of, Solis-Cohen. N. Y. Med. Jour., August 10, 1889.

Strums, operations upon, Hortley. N. Y. Med. Jour., August 17, 1889.

Tabes dorsalis, the suspension treatment of, Inglis. Amer. Lancet, August, 1889.

Two incomplete ovariotomies, Buchanan. Amer. Lancet, August, 1889.

Typhus and typhoid fevers, a mixed case of, Nixon. Med. Press and Circular, August 7, 1889.

Ueber das sog, Metamorphosirende Atmungs geräusch, Riefs. Deutsche Medicinal-Zeitung, 22 August, 1889.

Uber die Behandlung der Mastdaunfistel-Verchére. *Ibid.*

Ueber den Nachveisder Beweglichkeit pleuritischer Exsudate beim Lagewechsel. Archiv. für Pathologische Anatomie und Physiologie und für klinische Medicin, 1889, Heft 3.

Uober dos Alter, den Ursprung und die Benennung der syphilis in Bosnier und der Hercegorina, Glück. Archiv für Dermatol. und Syph., 1889, Heft. 3.

Ueber deir Verschluss der Arteria Mesaraica Superior durch Emboli, Kaufmann. Archiv für Pathologische Anatomie und Physiologie und für klinische Medicin, 1889, Heft. 3.

Ueber die Hypertrophie und das Physiologische Wachsthum des Herzens, Tangl. *Ibid.*

Ueber einen Physiologischen Unterschied der Haut des Europäers und der des Mafarén, Glogner. Archiv für Pathologische Anatomie und Physiologie und für klinische Medicin, 1889, Heft. 3.

Ueber Nocluläre oder folliculäre Antzündung der Schleimhaut der Harnnege, Pizenoski. *Ibid.*

Ueber Hydrargyrum Salicylicum, Hahn. Archiv. für Dermatol. und Syph., 1889, Heft. 3.

Ueber die Befandlung der chronischen Gonorhöe, Berdu. *Ibid.*

Vergleichende Untersuchungen, über die Ernährung mit gemischter und rein vegetablischer kost mit Berüchsichtigung des Eineissbedarfes, Kumogawa. Archiv für Pathologische Anatomie und Physiologie und für klinische Medicin, 1889, Heft. 3.

Zur Gynäkologischen Balneotherapie, Kleinwächter. Wiener Medizinische Presse, 4 August, 1889.

Zuckerharnruhr, Corpulenz, Gicht und chronische Merenkrankheiten, Camerer. *Ibid.*

Zur Keuntniss des Diphtherie bacillus, Zarniko. Centralblatt für Bakteriologie und Parisitenkunde, 18 Aug., 1889.

"In Severe Cases of Typhoid."

STRÜMPELL'S TEXT-BOOK, REFERRING TO DIET IN TREATMENT OF TYPHOID FEVER, SAYS:

"Milk is excellent and should be ordered, but
"will unfortunately not be taken continuously.
"In severe cases, Nestle's Mild Food (Kinder-
"mehl) has been often employed by us with
"benefit."—**Edition 1888, page 20.**

This extract from one of the best and latest Text-books in use at Harvard, Johns Hopkins and Columbia Medical Colleges, will be appreciated by the profession at large, many of whom have hitherto valued Nestie's Food solely on account of its superiority as a Diet for infants. **Would you like a Sample?**

CAUSES OF ACQUIRED INSANITY.

BY JOSEPH JONES, M.D.,

Professor of Chemistry and Clinical Medicine, Tulane University of Louisiana; Visiting Physician Charity Hospital, New Orleans, La.

WE have, after critical study and analysis, been able to refer those cases of acquired insanity, which have come under our immediate observation and professional care in Georgia, Tennessee, and Louisiana, to the following causes:

1. HEREDITARY CONSTITUTION OF THE CEREBRO-SPINAL NERVOUS SYSTEM, INDUCED BY INTEMPERANCE, SYPHILIS, AND OTHER CAUSES ACTING UPON ONE OR BOTH PARENTS, AS SELF-ABUSE, AND EXCESSIVE VENERY.

Hereditary insanity, implying hereditary weakness of the nervous system, generally comes on without the intervention of appreciable exciting causes.

The nervous system seems to be peculiarly liable to be involved in the effects of hereditary degeneracy, and this is frequently evinced by the occurrence of mental symptoms at those periods of life when either rapid structural developments take place, special functional altering is and was exhibited, or is ultimately arrested; or upon the advent of senile decay.

We have thus an insanity of pubesence, a climacteric insanity, and a senile insanity.

Idiocy and imbecility are also frequent results of hereditary weakness, showing itself during fœtal life, or during the period of dentition.

The insanity which often affects women at parturition, the insanity of pubescence, climacteric, and senile insanity, may often be traced to hereditary weakness of the nervous system.

2. MASTURBATION.

The excitement incident to the habitual and frequent indulgence of the unnatural practice of masturbation leads to the most serious constitutional effects; and in some cases to the loss of the higher moral feelings, entire degradation of the moral sense, and hopeless insanity.

The effects of masturbation are more especially manifested in the nervous system, the functions of which are more or less perverted. The mental faculties become more or less affected—there is great despondency, loss of memory, irritability, irregular action of the heart, derangement of digestion, prostration of strength, headache and neuralgic pains. There is a general loss of health and strength; chronic hypochondriacal invalidism, epileptic seizures, ending in many cases in impotency and hopeless insanity.

Guardians, parents and teachers, cannot be too careful in guarding those entrusted to their care from this most degrading and pernicious of all habits.

The effects of masturbation in inducing insanity, may be witnessed in its victim long after the cessation of the pernicious habit.

The child of the masturbator is liable to hereditary insanity.

3. ALCOHOLIC POISONING.

Alcoholic insanity is met with in three forms:

(*a*) Acute alcoholic insanity.

(*b*) Chronic alcoholic insanity.

(*c*) Delirium tremens.

(*a*) *Acute Alcoholic Insanity.*—Acute alcoholic insanity seldom occurs except where there is a strong hereditary tendency to mental disturbance, or when the cerebral energies have been notably impaired by excesses or over-work. When all these predisposing causes exist, it may not require a large dose of alcohol to bring on an attack.

Mania a Potu.—The most frequent form of the affection is known as *mania a potu*—a violent maniacal delirium, with a tendency to homicidal acts.

In some cases the mental disorder takes the melancholic form, and it becomes necessary to guard especially against the strong suicidal tendency which generally characterizes it; unless the brain has been weakened by repeated attacks, both forms are curable, and generally of short duration.

(*b*) *Chronic Alcoholic Insanity.*—Chronic alcoholic insanity is one of the results of chronic alcoholism, and illustrates in a forcible manner the solidarity of the psychical and somatic functions of the nervous system and the interdependence of these morbid manifestations.

The mental symptoms are generally present from the beginning, though not always prominent enough to attract special attention. The sleeplessness, so characteristic of the commencement of mental disorder, is an early symptom; then restlessness and depression, with suicidal tendency, sometimes passing rapidly into complete dementia; but generally passing through a course of mental and moral degradation, which progresses step by step with the symptoms of failure of physical nervous power.

Chronic alcoholic insanity presents many points of resemblance to the *general paralysis of the insane*, and is in some cases only to be distinguished from it by the presence of the mental depression, which is seldom more than a transitory symptom in the general paralysis.

(*c*) *Delirium Tremens.* — It is important to note that after the acute symptoms have passed away, in some cases, there is left behind a state of subacute insanity of a characteristic nature.

At first suicidal symptoms are apt to appear; suspicions of poisoning; fear of impending evil; and hallucinations of hearing, and sight are often frequent.

That ordinary *vinic* or *ethyl alcohol* is a sufficient exciting cause of alcoholic insanity is beyond doubt. The more concentrated the form in which alcohol is taken, the more surely and rapidly are its characteristic effects induced; and although some beverages give a greater liability to certain forms of disease than others, yet the ultimate tissue changes produced by all are practically similar, and of a markedly degenerate character.

The purest alcoholic fluids will also induce the *acute forms*, but some of the phenomena observed in the worst cases of alcoholic poisoning have been referable with some probability to admixture with *fusel oil*, *essential oil of wormwood*, *occulus indicus*, and other substances more deleterious than corn alcohol itself.

Chronic Habitual Drinking often Hereditary.—Chronic habitual drinking is undoubtedly hereditary in many cases, not that the ancestors have been necessarily drunkards, but that the family is of unstable nervous organization, and that the neurotic traits which show themselves in other members in such affections as epilepsy, hysteria, insanity, are manifested in these cases by an intense craving for alcohol.

Sometimes a pernicious education, by fostering habits of indulgence in early youth, has led to subsequent excess and chronic alcoholism, and the injudicious prescribing of stimulants has occasionally been productive of similar harm.

PATHOLOGICAL ANATOMY OF ALCOHOLISM.

It is well known to pathologists that a large amount of ardent spirits acts on the nerve centers as a narcotic poison, and causes rapid death by coma; smaller quantities produce intoxication, accompanied with or followed by an acute congestion and catarrh of the alimentary canal, especially of the stomach and duodenum.

Habitual dram drinking, by altering the chemical composition of the blood, and checking the normal changes of its corpuscles, exerts an injurious influence on the nutrition of the tissues. This is increased by the lessened consumption of food, and by the alteration in the caliber of the bloodvessels, set up at first by a special action on their vaso-motor nerves, and afterwards maintained by degeneration of their coats, as well as frequently of the heart itself.

Alcohol interferes directly with the nutrition of the cell elements of the various organs, including the cerebro-spinal system, as it circulates through them, and it retards the elimination of effete materials—carbonic acid, uric acid, and urea.

In chronic alcoholism the amount of fat in the blood is increased.

Chronic congestion and catarrh of the stomach, leading to atrophy of the glands, and an increase in the submucous connective tissues, is very common.

The liver is at first enlarged from congestion, and may continue so from a subsequent infiltration of fat, but more frequently it shrinks, owing to cirrhosis.

Lobar emphysema, chronic bronchitis, and hypostatic pneumonia are common.

The heart is flabby, dilated, and presents fatty infiltration, and even degeneration of its muscular tissue, but it may be hypertrophied, probably as a result of coexistent disease of the kidneys.

The arteries and endocardium are studded with small deposits; the capillaries are congested, and the veins varicose.

The kidneys exhibit the fatty, or more commonly, the granular form of Bright's disease.

The muscles are pale and flabby, and even in the bones the formation of fat takes place, at the expense of the bony texture.

The nervous centers are atrophied and tough, the convolutions are shrunken, the nerve cells and the nerve fibers are wasted, and an increased amount of serous fluid exists in the ventricles and subarachnoid space. The abnormal adhesion of the dura mater to the cranium, the large pacchionian bodies, the opaque

arachnoid and the thickened pia mater, all testify to an exaggerated development of fibrous tissue. Occasionally hemorrhage within, or softening of the brain, consequent upon the distended state of the bloodvessels, is met with.

We have in the preceding well-known pathological alterations, induced by the continuous and intemperate use of alcoholic drinks, an explanation of the terrible effects of intemperance in filling our jails, prisons, hospitals, and insane asylums, with miserable, diseased, suffering, and incurable human beings.

4. THE CONSTITUTIONAL EFFECTS OF THE ACTION OF THE POISON OF SYPHILIS.

Insanity may result from the degeneration of the ganglionic cells and nerve tissues, and from the formation of gummatous tumors upon various portions of the cerebro-spinal nervous system, consequent upon the action of the poison of syphilis.

When constitutional syphilis affects the brain and nervous system, the mental symptoms that arise are found in the majority of cases to present marked similarity in their character. The mental disturbance is generally preceded by distressing sleeplessness, which is generally followed by increased depression of mind.

Religious anxiety of a peculiar hopeless character frequently shows itself. Exaggerated self-accusings are earnestly uttered by those who have previously been unusually callous as to the results of their actions. The feeling of alarm which accompanies these symptoms sometimes develops into a violent excitement, which may be called maniacal.

The development of gummatous products within the cranium is frequently evinced by symptoms similar to those of general paralysis; during the progress of the disease, attacks of acute delirium are not unusual. Sometimes extravagant delusions, such as are frequent in general paralysis, are exhibited. Very generally the progress of the disease is characterized by a general falling into dementia.

5. EPILEPSY: CONGENITAL, HEREDITARY AND ACQUIRED.

6. RELIGIOUS EXCITEMENT.

The contemplation of certain hypotheses and dogmas, held and vehemently urged from the pulpit, by some religious sects, have, without doubt, produced great excitement and alarm in the minds of persons of excitable and unstable nervous organization. The burning eloquence and moral pictures of the religious enthusiast and fanatic, and the horrible revelations of the melancholy and sinister imagination of Dante, have converted the souls of the unwary and timid into the abodes of terror and alarm.

Certain dogmas, often represented and illustrated by this fiery language, and by the subtle power of the painter's brush, as the fires and tortures of a burning hell, a veritable lake of fire, where fiery billows eternally wrap the bodies and souls of the damned, and whose shores forever resound with the piercing, truly hopeless shrieks of those inhabitants of this earth who have failed to enter heaven, on account of the commission of personal sins; a veritable living devil, ever on the alert to seduce and damn the souls of men, women and children, and drag the unwary down to everlasting confusion and suffering in the bottomless pit—the *unpardonable sin*—have for centuries terrified the weak and timid devotees of certain phases of religious belief into hopeless insanity.

The violent exercises of certain religious sects, during the performance of *so-called* religious exercises, such as shouting, hopping, jumping, dancing, *demoniacal "holy" laughing*, often induce epileptic seizures, and inaugurate such congestion and exhaustion of the nervous structures as induce religious melancholy and end in hopeless insanity.

The hallucinations which in the experience of the author exercise the greatest influence on the victims of insanity are:

1. *The firm belief by the victim that he is the slave and the abject subject of the devil.*

To all remonstrances the victim replies that he must obey his *master*, the *devil*.

I have observed and treated cases where the victim of religious melancholy and hallucination has for days and weeks refused all food, because *his master*, the *devil*, commanded him not to eat. In some cases, every agent and every effort to induce the patient to take food have failed, and death has resulted from starvation.

2. *The commission of the unpardonable sin.*

3. *The eternal damnation of the human soul; lost, lost, lost forever.*

In all cases of insanity resulting from religious excitement which I have examined from their inception, the following appears to be the order of symptoms:

(*a*) Congestion of the brain, with more or less fever.

(*b*) Increased rapidity of the circulation.

(*c*) Persistent sleeplessness.

(*d*) Intense acting of the ganglionic centers of the brain, and especially of those connected with the imagination.

(*e*) High-colored urine, with an increase of phosphoric acid.

(*f*) Foul breath, furred tongue, loss of appetite and derangement of digestion.

I have never observed a case of so-called *religious insanity*, which did not present marked physical derangements in addition to the mental phenomena—the physical disorders often preceding and dominating the mental aberrations.

7. POLITICAL EXCITEMENT AND CERTAIN POLITICAL AND RACE CHANGES, SUCH AS THOSE WROUGHT BY THE GREAT AMERICAN CIVIL WAR, 1861–1865.

8. PERSISTENT, DEEP-SEATED AND UNCONTROLLABLE GRIEF, CAUSED BY DOMESTIC AFFLICTIONS, LOSS OF PARENTS, CHILDREN, WIFE, HUSBAND, ETC.

9. DISAPPOINTED AFFECTIONS, DOMESTIC QUARRELS, WITH THE ATTENDANT EXISTING UNHAPPINESS, AND OFTTIMES MORAL DEGRADATION.

10. SUDDEN REVERSES IN BUSINESS, LOSS OF PROPERTY AND MONEY.

11. Melancholia following gynæcological operations on the female genital organs.

The effects upon the nervous system of the numerous abdominal sections and frequent ablations of the uterus and ovaries, have not been fully described, and are subjects for earnest and careful investigation.

12. Climacteric Changes.

13. Sunstroke.

14. Remittent fever.

15. Morphine, cocaine, opium, tobacco and other poisons.

16. The action of various poisons, as those of malaria, lead, mercury and arsenic.

It would be foreign to the purpose of the author to discuss the effects of race, occupation, climate, age, education, and many other subjects upon the production, increase or decrease of insanity.

THE TIME ELEMENT IN OFFICE PRACTICE.

By F. W. HIGGINS, M.D.,
CORTLAND, N. Y.

I WISH to present for your discussion this question —Is it desirable or practical to devote to an office patient more time than is usually done?

This is a very busy world and doctors are very busy men. Many do not find time to attend medical meetings. Very many are too busy to eat or to get a full quota of sleep. Most are too busy to take a vacation. Probably one half cannot attend church regularly. Medical journals lie unopened, and many new medical books are unread for want of time.

The typical successful physician is a man busy in a private office, with a score of patients in the waiting-room. Regard for their time as well as his own almost compels him to hurry through the examination necessary to a diagnosis, and limit the treatment to a swiftly written prescription. It seems almost absurd to ask such a man to give more time to each patient.

But, it cannot be doubted, that in the heart of this successful busy man there are regrets that more minutes or hours cannot be spent with some dubious case. Or with the physician who is not so driven, but who turns off his patients with the same dash and dispatch, there must remain a lingering doubt of his real usefulness to society.

There is a story in a late journal "that there was, some time ago, a doctor whose morning levees were crowded beyond description. It was his pride and boast that he could feel his patient's pulse, look at his tongue, probe at him with his stethoscope, write his prescription, pocket his fee, in a space of time varying from two to five minutes." One day an army man was shown into the consulting room and underwent what may be called the instantaneous process. When it was completed the patient shook hands heartily with the doctor and said: "I am especially glad to meet you, as I have often heard my father, Colonel Forester, speak of his old friend, Dr. S." "What!" exclaimed the doctor, "are you Dick Forester's son." "Most certainly I am." "My dear fellow, fling that infernal prescription into the fire, and sit down quietly and tell me what's the matter with you."

While the plea of want of time must, with some, excuse this haste in dealing with cases, and the eclat of this condign manner of disposing of a patient recommend it to others, there are manifest disadvantages in the weak diagnosis.

Glaring blunders are unavoidable. Enteritis has been called colic; a dark brunette, with dyspepsia, has been called a case of Addison's disease; a truss has been ordered for a testicle in the inguinal canal, and itch treated as urticaria, all from neglect to look for easily detected signs.

The uncertainty of the facts collected in this hasty way often renders the scientific value of cases reported almost valueless. If a practitioner acquires this habit he is not accustomed to give to himself or to others a reason for the hope that is within him. His opinions on the prognosis or proper treatment of a case are not so fixed in his own mind that he is prepared to follow them to the extremity.

When it is possible to give time to a case, the patient's complaint can be often traced back to an ulterior cause, the removal of which, alone, gives us control of the secondary affection for which our advice was sought.

A headache may be due to a retroverted uterus, the only avenue of permanent relief; a dyspnœa should not be prescribed for until anæmia, valvular disease of the heart, emphysema, Bright's disease, or some of the other known causes are discovered. But an answer to questions of this kind does not lie on the surface; the physician must take *time* to give a definite one.

Since we now-a-days believe in treating persons, not diseases, the previous history becomes almost a necessity to the proper management of the present condition. But this takes *time* to elicit. More than that, the influence of hereditary tendencies is so strong that the family history must be obtained before we are satisfied with our comprehension of the case in hand.

The temperament and idiosyncrasies of the patient are also matters to be taken into consideration. These should be even noted in our case-books, if we would exactly apply a remedy which must be used for a long time.

This poor case-book is one of the principal sufferers from the lack of time. Large gaps, or a history, symptoms, and diagnosis comprised in a single word, attest the desire to speed the parting to welcome the coming patient.

Physical signs being often so easily detected by an educated ear or hand are less often slighted than other necessary points. The waste of time appears most in getting the patient undressed and dressed again. In heart murmurs and lung râles, however, it is not the loud, easily detected, blowing sounds that have the most significance. It is the still, small voice.

There are many finer aids to diagnosis sadly neglected for want of time to apply them. Urine analysis, by some used daily, is by others a rare feat, and then limited to boiling it. Often we do not have time to bother with a microscope. We treat ears by

syringing with warm water and a blister, because it is too much trouble to throw the light into them with a forehead-mirror.

But now, when we have taken time to gather all the symptoms, signs and history of the case, when a diagnosis of the disease, or rather the diseased condition is clearly made out, there comes the greatest temptation to slur over our remaining duty. Our scientific zeal is satisfied by detecting the signs of disease. We yield to the paralyzing pessimistic therapeutics of the times, and allow the patient to go away with a prescription for any one of the familiar preparations, or mixtures, which happens to come first in mind. It is just at this point, after the diagnosis is made and before the prescription is written, that time in the treatment of office-cases is invaluable.

We all exclaim against the evils of routine practice. Nor are we, as family physicians, justified in treating series of similar cases with the same remedy simply for the sake of comparing results. Fortunately we have hospitals where salol may be given to one hundred cases of rheumatism while another hundred are confined to antipyrin; but we have no right to perform these admirable experiments upon our private patients.

If we take a fee of our office-patient we are morally bound to give him the best treatment possible in the present state of medical knowledge. But the field of medicine is so broad, diseased conditions are so varied and modified, remedies are so numerous, and their desired good effect so often counterbalanced by the harm they may do, when given continuously, and the reflexes upon distant organs, both of the disease and the proposed remedy, so complex, that no rule of thumb will answer. It is here that the nice adaptation of means to ends, the faculty we call judgment, demonstrates the reliable, successful physician; this is the faculty that determines the value of the physician to the community. These judgments and decisions are not always forthcoming on the instant. To be valuable they must be the result of calm deliberation.

In our own affairs of importance we take time for the mind to act, "to make up our minds," as the expression is. Carpenter was the first to explain clearly how, by what he terms unconscious cerebration, the mentality absorbs the facts presented, which are elaborated and assimilated in the dark chambers of the mind beyond our ken, from whence in due time flashes back to our consciousness the conclusion. It is conclusions crystallized in this natural way in the deep recesses of our own minds upon which we will stake our reputations, and, if necessary, our all. They are a part of ourselves. If suddenly formed, we call them instincts. If no step in their formation is discovered, we may call them inspirations. This faculty is the *spirit* in man; the ego, the divine.

An invalid is incapable of determining what shall be the course to pursue to bring *himself* back to health. All the conditions in his case must be apprehended by the trained mind of the physician whom he employs. It is the crucible of another's mentality upon which he must depend for that polished product of the soul we call a conclusion. Should not the muffle have ample time to heat in an analysis so important and complex?

There are emergencies where conclusions can and must be formed at once. But the *finished* production is by letting the mind dwell on the matter, viewing it on all sides, sleeping over it. There is a sort of clairvoyant condition, an abstracted state, when the mind acts untrammelled, if time be allowed.

The idea that a physician, alone of any trade or profession, is to know all he is ever to know about a case on the spur of the moment, is probably a relic of the old superstitions when he was a magician, a necromancer, and his black art was not subject to mortal limitations.

To us younger men the practical question is, will it pay to spend so much time with a patient?

The uniform scale of prices is a great hindrance to attempting more thorough work. If we have fixed our rates at fifty cents, or one dollar, for an office call, there is an almost irresistible tendency, when fifty cents' worth of our time is used up, to turn off the patient. The usual rates are so low that one feels compelled to attend to a number of patients each day in order to make the month's receipts anything respectable. Then, from the first, we naturally copy the methods of older men who feel compelled to give their advice without going into the minutiæ of all the complaints of their patients. They get to consider many of the troublesome things, bookish and unpractical. We turn off our few patients in the same style as they, and then spend the rest of the office hour in solitude. If a physician's fee were graduated somewhat like an architect's, or a lawyer's, or even a plumber's, or a shoemaker's, more and better work could be profitably done on a case. Why should a physician alone, of all the professions or trades, not receive pay according to the time spent? A watchmaker or mechanic expects so much an hour for his time. Why should we not receive the same for work just as necessary, important and skilful?

Since there are but twenty-four hours in a day, it is in cases requiring time that the younger physician has an immense advantage over his longer established confrére. While one may have more experience, more patients in the waiting-room, a longer ride, and is apparently in a fair way to control the market, there are many important, tedious cases that the young man with *time* is far better qualified to treat. Indeed, it is just at this point that the reputations of many have been made; their best work done.

The treatment of orchitis by strapping the testicle, of dilatation of the stomach by lavage, of otorrhœa by boracic insufflations, of gleet by bougies, of catarrh by *any* method, require patience and *time*.

As the clientéle of the physician increases it is possible that the quantity of work done will interfere with its quality. It *must*, unless time is still given to the patient.

A dentist does not find it policy to put in a gold filling less carefully and thoroughly as his office fills with waiting customers, or they begin to tire and leave. It rather attaches us to our lawyer if we are told that he is very busy that day, but will see us tomorrow at three.

We now have a class of physicians called specialists, who do take all the time and pains necessary to cases in their particular line.

If a love of his profession, or what would seem sound business principles, compel the growing physician to still devote much time to each patient, he naturally becomes a specialist. He is necessarily a specialist, in fact, if not in name, in that branch to which most of his time has been devoted. If, in no other field, he becomes a specialist in that much neglected one of general practice.

A NEW NAME PROPOSED FOR THE VENTRICULAR BANDS.

By EPHRAIM CUTTER, M.D., LL.D.,
NEW YORK CITY.

IT is almost amusing to find out how little one knows, even after years of study, of a given subject. For example, the writer has studied his own larynx since 1862, inspecting his vocal bands, the ventricular bands, arytenoid cartilages, during phonation, cantation from to laughing, coughing, sneezing, respiration and deglutition, but it was not till 1884 that he had a clear idea of the function of the ventricular bands more commonly called "false vocal cords." To be sure he had traced the alarming, clangorous, peculiar cough in spasmodic croup (which is usually very alarming to all concerned) to be due to the thickening, probably almost œdematous condition of the ventricular bands. One case is particularly remembered of a young lady about eighteen years old who, apparently well, would at times exhibit this "croupal" cough. When this cough came on in school, it excited at first alarm in teachers and scholars all over the room. When the cough was produced under the laryngoscope, the contact of the ventricular bands was trifid, dividing the ventricular plane into three (3) equal parts like a circular disc cut into three equal portions. This was a unique curiosity, and seems to explain the peculiar tussive cough by the chronically swelled condition of the ventricular bands. The case should have taught that the ventricular bands are the chief physical agents in producing cough, by holding the breath back and fixing the diaphragm so that it presses the air forcibly against the closed ventricular bands, which, suddenly and instantly relaxed, allow the air to rush forth as if projected from a weapon, and thus the explosive sound is produced we call "cough," and the outgoing air expels whatever secretions may have been borne upward by the ciliæ of the bronchial and tracheal epithelia to where the air can reach. From this function in cough, the ventricular bands might be called cough bands or cords.

But their chief function in health is the holding of the breath. Prof. C. W. Emerson, Ph.D., principal of the Munroe School of Oratory, Boston, lately stated to his pupils "that for many years he had taught that the vocal cords were the chief agents in holding the breath and not the rigid setting of the abdominal muscular walls and diaphragm: that in normal breathing, the vocal bands close for an instant during expiration, and the action of the diaphragm and of the abdominal muscles thus arrested forces the inspired air into the apices of the lungs, expanding them in a normal manner and supplying fresh air, and that thus the full development of the upper chest was obtained and maintained in speaking and singing; that in unhealthy respiration the vocal cords did not close and hold in the air, and that hence flat, weak chests and weak voices were the natural consequences of the unresisted outgoing; that when he came across some articles on the subject,[1] he found it was not the vocal cords, but the ventricular bands that did this work of arrest." After this statement, the writer demonstrated on himself the fact that the ventricular bands close in order to hold the breath during phonation, etc., and that so far as can be seen the vocal bands have a rest during this function of holding the breath, which is of the greatest importance to speakers and singers who wish to do efficient work, and to bring the subject home to the medical man who reads a paper and to the audience who is listening to him.

In 1884, the writer appealed to the professional laryngologists to give a new name to the false vocal cords or ventricular bands, but as he has heard of no response to this appeal, he ventures now to suggest some names for approval—premising that the word "chords" or "cords" is not expressive enough of the situation—for to do so one has to imagine a cello D string, about one and one-quarter inches long, split longitudinally into two equal parts, a section of the end being a semi-circle; the rounded side of the string forming the bands and the squared side prolonged into the walls of the larynx. Imagine a cello string like this. How little music it would make. The fact is, the nearest analogy to the vocal bands is found in the lips of a player of a cornet, stretched over the embouchure of the mouthpiece; only the vocal bands are joined in front and opened behind, whilst the lips of the cornet player are joined at each side. The vocal bands are made tense by the stretching backwards of the arytenoid cartilages, etc., while the lips are stretched over the circular ring of the open mouthpiece. Players speak of "making a lip," but singers and speakers "make their glottis" instinctively.

The ventricular bands are illy named, because the ventricles they form with the vocal bands are accidental things and not important functions, of which we have spoken, to wit: the proper holding of the breath in respiration, phonation, cantation, sneezing, etc. Suppose we follow the nomenclature, vocal bands, then we might call the ventricular bands, (1) breath bands, (2) breath holders, (3) breath cords, (4) breath valves.

If, instead of the vocal bands for the true vocal cords, we say "voice bands," then the writer would prefer for the false vocal cords "breath bands," until some one else favors us with a better name. But as false vocal cords have gone, so shall ventricular bands

[1] (*a*) Gaillard's *Medical Journal*, October, 1884; (*b*) "Transactions Music Teachers' National Association" (America), 1887; (*c*) "Transactions International [illegible]gress," 1887, Vol. IV. pp. 101-111. (E. Cutt

go, as being inexpressive of the functions of the important mucous membrane, red-colored processes, or bands, that form the middle of the three valves of the larynx, to wit: (1) the epiglottis, (2) breath bands, (3) voice bands.

The closing of one after the other, beginning with valve three, Dr. Frederick Semeleder, now of Mexico, showed beautifully, in 1862, during the function of swallowing.

ACUTE CROUPOUS PNEUMONIA.

By E. B. CRONE, M.D.,
KERKHOVEN, MINN.

AT present I wish to report a series of forty-eight cases of acute croupous pneumonia. Beginning in November, 1888, there have been continuously cases of croupous pneumonia on my hands until June 1, 1889, and in the treatment of these cases there has been a splendid opportunity offered to test the different methods. My conclusions are that there is no specific for pneumonia, no one remedy that is safe to use alone, and that were I confined to one single remedy, it would be brandy. Brandy for the aged, brandy for the maiden, brandy for the baby. They will all take it; and nearly all get well in this climate. It is my impression that pneumonia in Minnesota is not as fatal and dangerous a disease as it is in the East; it has been my observation also that operations are more successful here than in the malarial districts of the Southeast. It is a rare thing for extensive suppuration to take place. I have had an amputation wound of the thigh unite without a drop of pus, and the patient discharged in fifteen days. It must be that the pure air, so heavily loaded with ozone, has a salutary influence on wounds and all kinds of "inflammations." In the forty-eight cases, I only lost two, both old men; one seventy-four and the other sixty-eight years of age. One of these I did not see until the fifth day, and in the other the fever had entirely subsided; but he died from exhaustion on the twentieth day of illness. In the first cases I used tincture of aconite, and antipyretic doses of quinine, with whiskey or brandy, at about the period of crisis. Some of my cases got very bad; if it had not been for the whiskey that I gave to counteract the damage done the heart by the aconite and quinine, the death list would have been large. I soon saw that aconite was an injury to my patients, and quinine also in large doses; then I tried antipyrin and antifebrin. Each case seemed to be slow to get up, and depressed. Wherever it was used it would lower the temperature, and give a deceptive appearance of crisis; then, in a few hours, the fever would rise higher than before and the patient become more agitated and nervous, and seem to have less resisting power. Those cases were among the slowest convalescents, so I discarded these drugs entirely in the treatment of pneumonia.

I used many different potions with negative results, but never failed to give brandy if the symptoms seemed bad; and in my last twenty-five cases my prescriptions would run like the following, quite in the stereotyped fashion: If called to the case with twenty-four hours after initial chill or stitch in the side, I would order:

Ammonii carb.	ʒjss.
Pot. citratis,	
Pot. nitratis	āā ʒiv.
Syr. tolu,	
Aquæ	āā ℥ij.

M.—Sig. One drachm every two hours the first day, and every three hours thereafter.

Morphine sulph., in one-eighth grain doses, was administered to give rest, and continued until about the fourth day. With a fever of 104 or more to begin with, by the fourth day it would not be over 102, and that is a safe temperature. Antifebrin had better be given to the dog than to the man now. On the fourth day I would change the recipe to about the following:

Ammonii carb.	ʒjss.
Tinct. cinchonæ comp.	℥j.
Spt. vini Gallici	℥xv.

M.—Sig. Mag. coch. every two hours; to be increased in quantity if a change in patient demanded it.

At this time I would also order two-grain doses of quinine every four hours, if the patient seemed weak and not standing the sickness well. About the time of crisis the heart failure was very prominent in some cases, and I would order the brandy mixture to be given every hour, and also strychnine sulph., gr. $\frac{1}{50}$, every three or four hours. Digitalis was used in the first of the series, but discontinued; it does not seem to be the proper heart stimulant. Whiskey and strychnine met the indications much better. When I was a student in the east my preceptor used to treat pneumonia with ergot, in some cases nothing but ergot, and it was astonishing how they died all around him; and they will die around any man that is looking for a specific for this disease. As for topical applications I tried poulticing, cotton wadding and the blister; but a short time ago I read in the proceedings of the New York Medical Society that a gentleman arose and read a paper on pneumonia, and therein stated that he could abort any case of pneumonia by the application of a blister to the side affected. I was astonished, for blisters are no new thing, they were used long ago, before he or I were born, and why has the disease been allowed to run and carry off the best of our race, if the application of a blister would abort it? The fact is it is not true. He overrated the usefulness of the blister in a manner that ought not to pass unnoticed; if there is a stitch in the side possibly the blister may give relief, but it is not sure, not near so positive as morphine. I tried the blister early and repeatedly, and it did not abort a single case. I am positive the statement the gentleman in Gotham made is incorrect. In cases of young children, I relied principally upon a wadded jacket, with an application twice daily of lin. tereben. and lini. ammon. to the chest, and after the seventh day, if the patient still had fever, my prescription would be:

Pot. iodidi	ʒii.
Ammon. iodide	ʒjss.
Ammon. carb.	ʒjss.
Tinct. sanguinariæ	ʒj.
Syr. pruni Virg.	℥iv.

M.—Sig. One drachm every two hours.

In some cases I gave also syr. ferri lodidi.

This would seem to hasten resolution, the brandy being continued until patient was able to sit up. Milk and egg flip, beef tea, gruel, anything and everything but heavy meats that we could get down were administered; the more the better, the more they took the less flesh they lost. This is about the treatment employed in the forty-eight cases, with a fatality of four per cent. in all kinds of unselected cases, and among these were several over sixty years of age, and many far out in the country, where daily visits were impossible. These are no new remedies that I suggest, but it is the proper application of remedies, the action of which is understood. In looking over the authorities in my library, Niemeyer, Bartholow, Eichhorst, Loomis, Pepper, Davis and others, I do not find the prescription for the early stages that I employ. Ammo. carb., they recommend, but in addition to that I add two valuable agents. At the beginning, when the fever runs high, there is almost a total suppression of urine, in some cases the system becoming overloaded with excrete materials that are normally washed away. The nerve cells and centers becoming burdened are irritated and various nervous phenomena appear, delirium, subsultus and the like. Now, my first prescription is the proper thing to wash those nerve centers clean, increase the quantity of urine, relieve the body of the substances that are poisonous. The temperature falls, the skin loses that hot, burning feeling, the mind becomes clear, and with the other remedies at crisis the patient is soon convalescent. On the other hand, bleed a patient into his own veins and weaken the heart, the same as aconite does, and you have all the conditions present to cause a fatal termination unless the attack is light or vitality great.

My paper is long, and I will not advance more reasons or theories for the use or disuse of other drugs, but the line of treatment above given is so satisfactory to me that I hope others may use it also.

Hydrotherapeutics.

By S. BARUCH M.D.
Attending Physician New York Juvenile Asylum and Manhattan General Hospital.

IV.

TECHNIQUE IN ACUTE DISEASES.

THE earliest application of water in the treatment of disease was in fevers. Simple ablution was in these primitive periods of medicine the method resorted to, and it stands to-day at the head of all hydriatic procedures in the initial stages of fever, independent of its course or type. The temperature of the water should be in accordance with the degree of temperature, elevation, and disturbance of comfort. Water at 60° F. is a safe average.

It is of the utmost importance in all fevers to begin treatment early, although it is impossible always to diagnose clearly the type of fever, the fact remains that the latter is a symptom, whose subdual contributes greatly to the diminution of danger, to the enhancement of comfort, and to the removal or prevention of local lesions. It is therefore incumbent upon the practitioner to resort to hydriatic treatment immediately upon being called to a case of pyrexia whose cause is not clear. If typhoid fever does not develop, the patient's comfort will be enhanced and his recovery from the less severe form of fever hastened; if it does develop, valuable time will be gained; sponging, as usually practised, is inefficient. While it somewhat refreshes the patient, the cooling effect is not maintained because the impression on the periphery is too evancescent. Ablution with the naked hand or with a small napkin combined with gentle friction is a better method, several folds of sheeting being placed upon the side of the bed opposite to that usually occupied by him. The patient is laid upon it, and each part of the body, with the exception of the feet, is successively dashed and bathed with water at 60°. If the temperature continues high after two days, the half bath is the next procedure. A bath-tub is placed near the bed, and filled with water at 65 to 70° for about ten inches. The patient, after bathing his face and head with ice-water, is seated in the bath and is now washed, under active friction, with the bath-water for fifteen minutes. During this time, every five minutes a basin of water at 60° F. is gently poured over his head and shoulders followed by friction with the open hand, dipped repeatedly in the bath water. A linen sheet having been spread upon the bed, the patient is laid upon it and wrapped in it from the neck to beyond the feet. If his reactive power is good, which may be readily discovered by the amount of hyperæmia of the surface which the hand friction has produced during the bath, the patient may be allowed to remain in the sheet and is covered with another, or with a thin blanket. If the reactive power is not good, he is rapidly dried with the sheet and covered with another, over which blankets are spread. The latter is rarely encountered in the early stage of fever. This bath may be repeated every five to six hours, so long as the temperature exceeds 103°. It may be continued for two days. If, on the fourth day, there is no abatement in the temperature, the full bath may be resorted to. We have shown by indisputable statistics that the full bath treatment, first suggested by Brand, has reduced the mortality from typhoid fever from 40 per cent. to 2 per cent. Never in the history of medicine have such extensive statistics been gather from such reliable sources. Figures often lie, but in this instance the source of the figures is so reliable and yet so varied that no judicial mind would refuse them credence.

Granting therefore that the method introduced by Brand is the ideal bath, followed by ideal success, the technique of this method becomes of immense import.

The modified baths above referred to will have prepared the patient for the adoption of the more strict measures. Ziemssen's graduated bath is another step in this gradual preparation. It is advisable until the diagnosis of typhoid fever is clear, when no deviation should be made from the strict Brand method. A tub is placed near the patient's bed and filled two-thirds with water at 95°. The patient being placed

in the water in the sitting or recumbent position, as may be indicated by his condition; cold water is gradually added, while he is being bathed with gentle friction, and the water is constantly agitated. Warm water is withdrawn and cold added until the bath water presents a temperature of 68° F. The duration of the bath should be half an hour; the first bath may be even as high as 75° F. Patient is then wrapped in a linen sheet, dried and covered, and a stimulant administered. This bath should be repeated, say every three hours, so long as the temperature reaches 103° F. It may be continued until the diagnosis of typhoid fever is clear. Now, the tub should be filled with water at 65° F., the patient's face, head and chest having been bathed with ice water, he is gently placed in the bath. Two attendants gently rub the surface with open hands, so that the superficial vessels become dilated. The patient remains in the bath fifteen minutes, or until decided chattering of the teeth indicates that the cooling process has proceeded far enough. Simple palla or small pulse, which may be due to contraction of the superficial vessels by the cold, should not deter the attendant from continuing the bath. The patient is now wrapped in a linen sheet. If his reactive power is good, as evidenced by a hyperæmic skin, he is allowed to dry in the sheet, if not he is dried, warm bottles are placed to his feet, the lower extremities are wrapped in blankets, and a stimulant is administered.

A compress of four thicknesses of old linen reaching from the axillæ to the pubis and covering the entire anterior portion of the body from the axillary line on one side to that on the other, is wrung out of water at 60° and laid singly upon the surface. This is renewed every ten or fifteen minutes.

After patient has been made comfortable, the temperature is taken in the mouth for the purpose of recording. If this be delayed long, sleep may ensue as a result of removal of the disturbing elements of pyrexia.

The bath is repeated, without reserve, every three hours, so long as the mouth temperature reaches 103° F. Natural sleep should not be disturbed, but stupor, listlessness and a dull sopor demand the repetition.

The water need be renewed only every twenty-four hours, unless it has been soiled by the patient.

The rationale of the bath treatment and several of its modifications in the complications of fever will be subjects of the next article. The reader may here be reminded that the chief merit of all hydriatic procedures lies in the fact that they are based upon rational, physiological data, whose delineation forms the most interesting feature of the teacher of hydrotherapeutics. Unfortunately this cannot be maintained of medicinal remedies, whose value, however, I am far from underrating.

INFANTILE CARDIAC HYPERTROPHY (Copland).—

℞.—Infusion of digitalis . . . . . 220 grs.
Nitrate of potash,
Syrup of orange flower . . . āā 8 grs.
Dilute prussic acid . . . . . gtts. 14.

M.—Sig. One teaspoonful every two hours (for a child of five years).

HYSTERO-EPILEPTIC ATTACK.

M., aged thirty, white, single, school teacher; decidedly neurotic type of constitution inherited from father. Ever since girlhood has been the victim of fainting spells and spasms. Health is otherwise generally good. Bowels, appetite, and menstruation regular. Suffers occasionally from headache. Uusually a drachm of the tincture of valerian has sufficed to break all former attacks of spasm, which were generally preceded by some physical or mental strain, quickly followed by more or less vertigo.

History of present attack: Menstruation occurred twice in the month, and both times was scanty and painful; walking had been indulged in to excess during the day of the attack, which occurred at 7 P.M. Dizziness and a dull headache. All of a sudden, while dressing for tea, patient was seized with general convulsions and clonic spasms over the whole body, accompanied with an intense throbbing pain in the head. As usual, the valerian was administered, without any effect. I was summoned about three-quarters of an hour after the attack began.

Patient was then trembling violently from head to foot, so much so that five or six persons were unsuccessful in their endeavors to hold her quiet. Every few minutes she would scream out and grasp her head, complaining of the intense pain. Consciousness was not entirely absent, though the mind was far from clear. The surface of the body and lower extremities were at first cold and cyanosed, afterwards warm and flushed. Slight opisthotonos was present. Eyes strongly turned inwards (internal strabismus). Hands clinched, and had to be held to prevent her seizing and tearing her hair. Teeth were strongly pressed together; mouth frothy; no biting of the tongue. Pupils could not be examined in the darkened room as carefully as was desired, and a light brought near the bed caused renewed excitement and terror. Pulse slow, full, and normal in beat. Temperature normal, as taken by the thermometer under the arm. No involuntary evacuations. Respiration slow and slightly labored, but very regular. Skin at first cool and clammy, then warm and ruddy.

At once administered a hypodermic of morphine (gr. ¼) in left arm, repeating the same in the right arm about twenty minutes later. Ice and iced cloths were applied to the head, and strong mustard applications were made to the soles of the feet. About a quarter of an hour after the second hypodermic, began giving 10 gr. of potas. bromid. in a little iced water every fifteen minutes. Room was kept as dark and still as possible. Pressure was made on certain of the nerve trunks, but without any perceptible effect.

In a short time the spasms and general convulsions became less violent, while the delirium increased. Every shadow and slight object in the room was taken for a "snake and his green eyes." Consciousness became a little clearer, but only during short, widely separated intervals. There would be a comparative calm for about five minutes, followed by a

sudden wild stare and a cry to take away the "snake" and remove the "worms" and "bugs" crawling on the bed and over the skin. Pulse grew slower and weaker; skin became hyperæsthetic, and there seemed to be considerable muscular soreness. Pain along the spine, and especially of the head, was complained of. The consciousness and delirium continued to rapidly alternate. The bromide was continued until nearly sixty grains were given. I then left the patient for three-quarters of an hour, as she seemed easier, though the tremblings continued vigorously. When I returned the tremblings were increasing and the delirium was still violent. Forty grains of the bromide were administered at once, the room made totally dark, and all attendants dismissed save one. The ice and counter-irritants continued as before. Some singing, as I requested, was started in the house, and the patient's attention being drawn to it from her own terrors, she fell into a short, quiet sleep of about twenty minutes. From this she awoke perfectly conscious, and inquired what had happened and where she was. Her whole manner and speech betokened that she was totally ignorant of what she had passed through. This was about an hour and a half after I had first seen her. Pulse and respiration were now slow, feeble, and regular. Tremblings still continued, but very much less marked in character. Exhaustion was great. As patient seemed inclined to sleep, she was left alone with a single attendant.

Called in the morning and found that the sleep had continued till 5 A.M., but not as profoundly as had been anticipated. Tremblings were now mainly confined to upper limbs, and were very slight, coming on only about every fifteen or twenty minutes. Just before daylight patient had urinated and taken a drachm of ol. ricini, as ordered. Pulse, temperature, and respiration about normal. Exhaustion great, muscular tenderness excessive, particularly about the arms; consciousness perfect, and all delirium absent.

Ordered to be taken every two hours:

℞.—Tr. belladonnæ . . . . . gtt. v.
Morphin. sulph. . . . . gr. 1-24
Aquæ . . . . . ʒj.

Absolute rest, plain, nutritious, chiefly milk, diet was ordered, with occasional cool sponging, if the last was not too disagreeable on account of tenderness, etc. In a few days patient was rapidly improving and sitting up, weakness and some soreness of the head being all that was complained of.—*Mettler.*

OBSTINATE EPISTAXIS.

R. S., aged twenty, came to see me with blood flowing from her nose so profusely that in five minutes her handkerchief was completely soaked. Her family history was good; she, herself, was of the hemorrhagic type, and had suffered frequently from nose-bleed, though not so severely nor for so long a time as this; menses, bowels, and appetite normal. The present attack began on a Monday, while the patient was engaged in washing. She had been under treatment with another physician, visiting him twice a day, to have her nostrils plugged and to take medicine, but the hemorrhage continued, the blood running forward over the lips and backward into the throat.

When I first saw her, the following Thursday afternoon, I tried douches of iced water and vinegar, iced salt water, tannic acid, boracic acid by insufflation, but without the desired result. I then dipped a piece of cotton in Monsel's solution and plugged it as far as possible into the nostrils. This checked it somewhat, but upon withdrawing the plug some time after there was a slight oozing of blood still. I then put some of the Monsel's solution in water (about ʒj to ℥iv) and sprayed it through an atomizer well into the nares. This stopped the hemorrhage completely, both backward and forward. This took about three-quarters of an hour. Soaking a large piece of raw cotton in the diluted Monsel's solution, I stuffed both nostrils with it; gave a prescription containing in each dose, ext. ergot, f℥jss, tr. aconit. rad., gtt. jss, syrup of ginger and water, to be taken every hour until two doses had been taken, and then once in four hours, telling the patient to return in evening if there were any signs of bleeding again.

Patient did not return until next morning, when I removed the cotton and found a very slight oozing of blood. Again, the diluted Monsel's solution was used through the atomizer, the nostrils stuffed with the soaked cotton, and the prescription continued every four hours. Patient complained of some weakness. Patient again called following morning, when I found that the hemorrhage had ceased entirely. I then syringed the nostrils with cold salt water, thus removing some of the larger clots which still remained in the upper nares. The ergot mixture was diminished in frequency and quantity, and the following powder ordered to be used by insufflation:

Acid. boracic, } p. e.
Pulv. amyli, }

More than five months after patient told me that she had up to that time no return of the hemorrhage.
—*Mettler.*

RED CROSS FIELD HOSPITAL, JOHNSTOWN.

SOME amusing cases that applied to "The Red Cross Doctor from Philadelphia" for treatment.

CASE I.—A man who had spent $500 in three years trying to get a pain in his back cured. The first doctor had started with a slight diuretic, and gone from that to a milk diet, blisters, and porous plasters. Finally, it had been agreed to apply the *hot* iron to his spine as a last resort; the flood, however, prevented that.

Raising the heel of one foot three-quarters of an inch higher than the other *made "a miraculous cure."*

CASE II.—An old man walked forty-five miles in from Bedford County to get a cure for his son, who had fits. On my telling him that I could do nothing without seeing the boy, he started home saying:

"He always did hear them hospital doctors was bent *on examining everything.*"

CASE III.—A man, one week after having two toes amputated, walked ten miles into town to ask if it had been "done right." He returned contented

home on my telling him that *it couldn't have been better.*

CASE IV.—A girl, nineteen years of age, who had been married four years, blushingly informed me that she had an "anterior retroflexion" of the uterus, consequently she was without children. She simply wanted some medicine to put her parts back in place. On my asking if her husband was a healthy man, she said "she couldn't see how that made any difference about her having children."

This being such a *serious* case, I thought best to call Dr. Biddle in consultation. She expressed such virtuous horrors at the mention of an examination that we put her on the heroic treatment of quinine sulph., one grain, in a glass of water at each meal, and succeeded in getting the uterus about twelve inches nearer its proper place. She feels confident now of raising a large family thanks to her books.

CASE V.—An attractive girl of twenty-three was sent to me as a possible case of diphtheria complicated with mumps. On being told that honest confession is good for the soul, she admitted that two years before a bad young man had taken advantage of her. Hydrarg. prot. iodi. gr. ¼, t. i. d. Result: Discharged in two weeks with good advice and box of pills, but *no* swelling in the neck.

A man asked me calmly if I had any fluid extract of peraxicum, as he was troubled with "a chronic torpidity of the liver," and feared he had "some hepatic bronchitis."

A Western Union lineman fell forty-five feet from a telegraph pole and came in to have me remove a splinter from his finger.—*Dr. H. A. Starkey.*

IS "HIGH" GAME POISONOUS?—The vitiated appetite which can only relish game when it has become "high," or in plain English putrid, is not likely ever to become popular. Poor people generally find it hard enough work to get ordinary meat, and have neither the means nor inclination to indulge in such a questionable luxury as "high" game. The question at the head of this paragraph, however, is one which affects rich and poor alike, to some extent, because stale and putrid meat of any kind is equally unwholesome. Dr. Lauder Brunton has been investigating the subject, and some of the results of his investigation are dealt with in an article in *The Hospital.* Dr. Brunton finds that when meat has become tainted there may always be found in it putrefaction microbes. These microbes, it is true, may be destroyed, and so rendered harmless by a sufficiently high temperature—that is to say, by a temperature sufficiently high to thoroughly cook the meat. That being so, the question arises how can the meat retain its poisonous qualities? The answer to this is that the microbe may not be the only cause of putrefaction, or even the direct cause of putrefaction at all, but if the microbe secretes a poisonous substance ten times more energetic in action than itself, and if this substance is of such a nature that heat does not destroy its deadly activity, the evil consequences of eating tainted meat will be the same whether the meat be cooked or not. Meat which has become tainted by the presence of putrefactive microbes may possibly be cooked sufficiently to destroy the microbes themselves, whilst the ferments they have formed continue to decompose the meat, and give rise to poisonous substances. That the action of the ferments are not destroyed by cooking is apparent from the fact that if such cooked game is kept uneaten for a short time decomposition is at once seen to be at work. Such being the case, the wonder is that poisoning by ptomaines—as the poisons generated by bacterial action are called—is not more common. Still, there is no doubt that the frequency of attacks of diarrhœa in summer time is largely due to this cause; and those who would avoid this malady will do well to eschew the use of "high" game or tainted meat of any kind.—*Globe.*

CONTIBUTION TO THE SURGERY OF THE ABDOMEN.—Dr. J. S. McArdle, of St. Vincent's Hospital, Dublin, describes an instrument consisting of a strong rubber balloon, a manometer, for determining the pressure used in distending the bowel, and a long connecting tube for attachment to the stomach or rectal tubes. For the purpose of inflation of either the stomach or intestines, pure hydrogen gas is employed with a pressure of from one-half to three pounds to the square inch. With this instrument he claims can be determined:

1. The position of stricture of the bowel.
2. The presence, and often the position, of perforation, ulcerative or traumatic..
3. The position of tumors, and their relation to the gut.
4. The condtion as to dilation, etc , of the stomach or intestines.
5. The position of the pylorus, and the amount of infiltration present, if any.
6. The fixity or mobility of any tumor of the stomach.

He illustrates his article by six cases occurring in his practice, in which he used the instrument as an aid in his diagnosis.

—Dublin *Journal of Med. Science*, August 1.

DR. WILLIAM C. WILE has discovered a new solvent for diphtheritic membrane in sulphocalcine. In the last number of the *New England Medical Monthly* he reports a grave case of diphtheria which was treated with the bichloride of mercury, one-twenty-fourth of a grain every three hours, brisk catharsis, and an hourly gargle of equal parts of sulphocalcine and water, with most favorable results. Injudiciousness on the part of the patient brought on what seemed to be a hopeless relapse, calling for a most unfavorable prognosis. The bichloride was increased to every two hours, and the membrane painted every fiifteen minutes with an undiluted sylution of sulphocalcine. The half-and-half gargle was continued every hour. The membrane commenced to fade, and in twenty-four hours scarcely a vestige remained. The recovery was slow and tedious, but complete.

THE IMAGINATIVE FACULTY.

THE author of Barnaby Rudge makes old John Willet exclaim, as he glances over his shoulder into the bold face of that arch-rascal Hugh, "there is no imagination in his eye," meaning thereby that his countenance does not exhibit any particularly good qualities. Here we have an instance of the closeness with which Dickens read human character. Criminality and insanity are so nearly related, and the acts of the one are so similar to those of the other that it is ofttimes difficult for judge and jury to decide where one ends and the other begins. Sir Crichton Brown has declared in his address before the late meeting of the British Medical Association that no class of people exhibit a greater want of the imaginative faculty than the insane. Now and then a few cases believe themselves to be great personages or monsters of some sort, but the vast majority are mentally vacant, listless and inanimate. The imagination, when properly developed and exercised, is an evidence of sound mental condition. It is a kind of balance-wheel maintaining a wholesome equipoise between the crude sensations on the one hand and the rational faculty on the other. Its over-activity will lead to as disastrous results as its under-activity.

Modern medical thought, fostered to a great extent by the recent brilliant discoveries in the physiology of the nervous system, is tending too far toward crude materialism. Mental phenomena are somehow intimately associated with cerebral activity, but the latter is in no way a clear explanation of the former. There are some states of the mind for which all the motor and sensory functions of the brain afford no causal basis. There are some manifestations of mind, whose expressions are always from within outward, and which are not at all necessarily dependent upon any antecedent percepts. Such, for instance, is the imagination. But as we have just said that cerebral and mental activity travel *pari passu*, and are somehow intimately associated, it follows that imagination will be influenced by bodily states and *vice versa*. Hence every true physician is, and must be, more or less of a psychologist, when he attempts to solve for himself the full significance of the symptoms of disease. A similar inflammation in two persons will not produce exactly the same kind of a pain; if it did, we might be inclined to have a little more faith in some of the teachings of homœopathy. A physician must, therefore, train himself and instruct his patients to exercise as well as control such oft-neglected faculties of the mind as the imagination. We once made the statement to a popular lecture audience that much of the mental decay observed nowadays in overworked business men is not due to too much exercise of the brain but to a bad distribution of the various kinds of work imposed upon it. An accountant, for instance, may work never so hard as a scientist, but he sooner complains of mental exhaustion because he has exercised but one side of his brain power in the handling of figures, and has totally neglected the creative and imaginative faculties. Such a man needs not idle rest but change; he needs to continue the exercise of his intellect, but in other widely different lines of thought. The imaginary is one of these lines too much neglected in this practical money-seeking age.

Sir Crichton Brown has noted that most of the great discoveries, such as those of Harvey and Newton, have been made under the stimulus of the imagination. To perceive and then to form a theory which is subjected to the severest test is the method usually adopted by the greatest scientists. The forming of the theory is the work of the imaginative faculty aided by the reason.

Among the sick a vigorous imagination is a powerful factor towards bringing about a cure. Every practical physician knows how a hopeful state of mind, dependent upon the building of bright air-castles, or the reverse caused by mental visions of gloom and despair will affect the appropriate action of drugs. But even in health the imaginative faculty enters into the well-being of the individual to such an extent that by it alone the state of the constitution can almost be detected. The reading of fiction has increased marvellously these latter years. The sharp competition and nervous strain demand for their relaxation increased play of the imagination, hence art, poetry, and theatrical amusements are more popular than ever, as evinced by the attendance in the great art galleries and opera houses of the old world and of the new. The physician's life particularly needs relaxation of this sort, and the contributions of medical men to the departments of imaginative work have been considerable. We need but mention the names of Akenside, Blackmore, Goldsmith, Smollett, Erasmus Darwin, Crabbe, John Brown, Oliver Wendell Holmes, and our own Weir Mitchell. Keats was apprenticed to a surgeon at St. Thomas Hospital, and Shakespeare's knowledge of medical matters would naturally lead to the supposition that at one time he must have walked the sick-wards. Once Sir Richard Blackmore asked Sydenham what course of study he would recommend for a medical student. The latter replied: "Let him read 'Don Quixote,' it is a very good book; I read it still." Conolly, in his latter years, took renewed delight in "Gulliver's Travels." Many of the most distinguished and busy physicians of the day are habitual novel readers. One of the greatest of living surgeons declared that on his way to and from every serious operation he dipped into Shelley, while another betrayed a close study of Keats in one of his recent addresses.

Statistics have been collected from the great libraries to show that the maximum amount of light literary reading is done in March, about that time of the year when the maximum amount of nerve exhaustion begins to declare itself. In the fall, when people are fresh from the rest of their vacation, scientific and mathematical works are much more in demand. The book trade stands as a proof also of the same tendency on the part of the masses to turn to the works of imagination when they are wearied with toil and mental strain.

This appeal on behalf of the imaginative faculty is both timely and well founded. Coming from a man like Sir Crichton Brown, who has given more than ordinary study to mental diseases, it will doubtless attract special attention. We are aware that there are doctors who, automatic like, are carried from one patient to another merely to give a name to the disease, and then pour down the patient's throat their potions and pills; such men will decry theorizing and any exercise of the imaginative faculty. They are a class of men who only have a laugh for hysteria and a sneer for hypochondria. They can see no further than the ends of their own noses, and believe nothing but what they do see; yet when a Faraday, a Davy, a Darwin, or a Lister have been urged by their dreams and ambitious hopes to increase the happiness of humanity with their great discoveries, the faithless small men are the first to avail themselves of the new advantages. We need more theorizing, more exercise of the imagination in working out our medical problems; but all theories should be thoroughly tested before any thought is taken of putting them into practice. Whole libraries of reported facts and cases will be as nothing until some one uses them to prove a theory that he may have imagined. The older astronomers collected facts for centuries before Tycho Brahe began to prove by them some notions he had about the movements of the celestial bodies; and what he began to dream and see partially realized Kepler established completely. A wholesome development and exercise of the imagination is one of the best means of preserving the mental equilibrium, and accomplishing the greatest amount of intellectual work. In health and in disease, in toil and in recreation, the imagination is a faculty which, if weak, should be cultivated; if normally developed, should be trained and kept under control. The moral and physical tone, not only of individuals but of society, will be elevated and strengthened by the care of all the mental faculties, and in these grinding, busy days none is in such danger of being neglected to the detriment of the highest mental capabilities as the imaginative faculty.

THE ARMY MEDICAL CORPS.

WE are continually hearing of the overcrowded condition of the medical profession. There is undoubtedly much truth in the assertion, though it can be said of nearly all the professions, particularly in and about the great cities, where competition is so sharp and where every kind of calling is more or less overdone. Not often does a young practitioner without money and influence have an opportunity to display his knowledge and ability. A small minority may be so fortunate as to receive an appointment upon some hospital or dispensary staff, but this field, comparatively speaking, is very small. And though the schooling of the resident or assistant physician is a capital one, few are able to sustain the expense of such a life for a long stretch of time, as either no salary at all or merely a nominal one is paid in such positions. By far the

larger number of graduates either depend upon the support of their friends and relations or use what little savings they may have acquired during their business life before beginning the study of medicine. Others try it for a time, and though finding the profession to their tastes and desires, are nevertheless compelled to take down their signs, put away their diplomas, and seek a more immediate livelihood in some mercantile business. Occasionally a young man will start in the country or some village and succeed, while in a great city, surrounded by rivals older and better known than himself, he would have proved a dead failure. We are sorry to know that too many men rush into the study of medicine, hoping to find it a life of ease and large fortunes, without well weighing in their minds its hardships and privations. The habit, which is common among some, of keeping up a fine establishment, in spite of all hazards, is misleading to many a new recruit to the well-filled ranks of the profession. Someone once declared he knew of many a fine rig that carried a hungry doctor at racing speed to patients the number of whom could be represented by ten omitting the one.

Sometimes young men do fairly well by receiving a position as surgeon on some of the transatlantic steamers, but aside from the difficulty of obtaining a position for which the British graduates are preferred, the life is an idle one, and its practice rarely gets beyond the administration of a brisk purge for seasickness, biliousness, or headache. No ambitious man will be long contented with such a life.

The Army and Navy, on the other hand, are in need of bright, capable medical men, and afford a very fair opportunity for general practice. In certain respects the Army offers greater advantages than the Navy, and we have often wondered why it was that more men did not apply for it's positions. A comfortable salary is paid, followed by a pension when the incumbent is no longer able to fulfill his duties, and opportunity is afforded frequently for one who is so inclined to extend his sphere of activity in laboratory work and special lines of research. Certainly the inducement is strong for one to enter the Army as a surgeon, who is unable or does not care to pass through the tedious years of waiting for a general practice.

On another page will be found a notice issued from Washington by the Surgeon-General, stating that the Army Medical Board will be convened in New York City, October 1, 1889, to examine those who may present themselves with their invitations before it as candidates for appointment in the Medical Corps. There are nine vacancies to be filled in the grade of assistant surgeon. The necessary requirements are fully stated in the said notice, and all further information may be obtained by addressing the Surgeon-General U. S. Army, Washington, D. C.

THE colleges are reopening and clinical material will be more plentiful.

HYPERIDROSIS OF THE FEET.

THIS affection, though apparently trivial, gives rise to great discomfort to the affected individual as well as to those who are in immediate contact with him, and not infrequently it has proved to needy persons an obstacle to obtaining employment.

Many years ago, Hebra taught that the emplast diachyli was a specific for this ailment. But this remedy has not borne out the author's views, for since his time numerous washes and powders have been brought forward, and to-day a quack remedy is advertised in the German medical journals as a "liquor antihidrorrhoicus."

The Germans seem at last to have discovered a valuable remedy in solution of chromic acid. Though inclined to a therapeutic inhibition, the German physicians now and then bring forward statistical evidences of the results of treatment whose large and carefully gathered data disarm skepticism at once. In the Prussian Army the sweating of feet has become a great nuisance, to whose abatement the medical staff has long devoted its best energies with more or less success. Recent reports to the Medical Department of the War Office, present the results of the application of a 5 to 10 per cent. solution of chromic acid in 18,000 cases. A complete cure was effected in 42 per cent.; an improvement in 50 per cent.; and in 8 per cent. failure is recorded.

A large proportion of the Army surgeons regard the solution of chromic acid as the most rapidly acting and effective remedy; others regard it as at least equal to the salicylic preparation. The marching capacity of men suffering from sweating feet was considerably increased.

The remedy is easily applied; it is cheap and cleanly; it is harmless if the precaution be taken to heal abrasions or wounds before applying it, and if the latter is done by the physician or under his supervision. The feet should be thoroughly bathed and dried before retiring; the soles and interspaces between the toes should be penciled with a brush several times in succession, and in eight or ten days the painting should be repeated.

ONE of the valued members of our Association, Dr. W. F. Hutchinson, of Providence, R. I., has just accepted the chair of electro-therapeutics in the University of New Hampshire. The importance in which this specialty is held is indicated by the fact that a full chair is assigned to it and not an assistant or adjunct. It is believed that this is the first full chair on electro-therapeutics as yet created. Dr. Hutchinson is the author of a very useful manual upon electro-therapeutics, which has been so well received by the profession that a second edition is now being prepared. If the graceful address made by Dr. Hutchinson, at the banquet of the American Medical Editors Association, be a sample of his qualities as a lecturer, he will be an acquisition to the teaching force of the University.

Annotations.

UTERINE MYOMA.

DR. TAIT, in a clinical lecture, strongly advocates the treatment of uterine myoma by removal of the uterine appendages as opposed to hysterectomy or intra-uterine electrolysis. "Myoma," he says, "is a disease of menstruation, and upon the arrest of menstruation only does its cure seem to depend, whether by nature's own efforts or by an imitation of them. Removal of the appendages is a scientific proceeding for the imitation of nature's own method. Hysterectomy is a coarser and much more dangerous method of accomplishing the same ideal." He firmly believes that many cases which are lost would have been saved had it not been for an improper delay in the performance of the operation.

—*British Med. Journal.*

LEPROSY.

A SUMMARY of the cases of leprosy occurring in the Hospital of San Lazaro, in Lisbon, during the two years, 1866–67, is presented by Dr. Donnet. Two types are described, lepra anæsthetica and lepra tuberculosa. The former is characterized by a greater loss of anæsthesia, a contraction and loss of fingers and toes, and an atrophy of the muscles of both hands and feet; the latter by a generation of successive tubercular growths over a part or whole of the body, a corrugated and thickened state of the skin, and a loss of the hair of the head and of other parts of the body, the distinguishing difference between the two being due to the choice of place of the deposited lymphoid matter.—*British Med. Journal.*

THE DISPENSARY NUISANCE.

THE *British Medical Journal* has for some time been giving considerable space to contributions on the Abuse of Hospitals, the same subject in meaning, and an attempt is making to stir up such feeling in the matter that some radical move will be made.

We have called attention to this nuisance before, and wish that the profession in our large cities could be sufficiently aroused to the importance of this evil to take concerted action for its repression.

The receipt of needless charity is apt to lower the moral tone of the recipient, and thus an injury is worked both to the individual and to the community. In some of the English hospitals they are now making inquiries into the financial condition of would-be patients. Would it not be well for us to do likewise?

Free dispensaries are so plentiful that they almost bid for patients, and they are attended, in great measure, perhaps mainly, not by those who are unable to pay, but by those who do not choose to pay for what they might get for nothing; at least if dress is any criterion. These dispensaries do not particularly affect the more prominent physicians, their patients are usually of too high a class to accept gratuitous treatment, but the ill results fall on the ordinary doctors; those who treat the masses.

ANTACIDS.

AN estimate of the relative antacid potency of the various articles in common use, as *gastric antacids*, may be obtained from an inspection of the following table taken from the address delivered by Sir William Roberts, M.D., F.R.S., at the opening of the Section of Pharmacology and Therapeutics at the annual meeting of the British Medical Association held in Leeds during the last month. Ten grains of the bicarbonate of soda are taken as a standard antacid dose, and the quantities given of the other articles correspond in saturating value to this standard dose. The results were obtained by direct alkalimetrical determinations, and are here shown in round numbers:

TABLE OF ANTACID EQUIVALENTS.

10 grs.	sod.	bicarb.	=	12 grs. pot. bicarb.
"	"	"	=	6 " creta precipit.
"	"	"	=	6 " carb. magnesia.
"	"	"	=	3 " calcined magnesia.
"	"	"	=	6 fluidounces lime water.
"	"	"	=	2 fluidrachms liq. potas.
"	"	"	=	1 bismuth lozenge, B. P.
"	"	"	=	2½ Wyeth's soda-mint tab.
"	"	"	=	5 vichy lozenges.

In speaking of *renal antacids*, the lecturer goes on to say, that "the essential thing in the prophylactic treatment of uric acid gravel is to guard the urine from precipitating within the precincts of the kidney. And we shall practically have attained our object if we succeed, not in altogether presenting precipitation, but in postponing it until the urine have quitted the kidneys. A postponement for a short time, even half an hour, may make all the differeuce between a precipitation which is fraught with pain and peril, and a precipitation which is practically harmless. Now, the protective effect of the antacid extends in this respect a good deal beyond the point at which the urine is rendered actually alkaline. For although all acid urines of medium density precipitate uric acid sooner or later, the time of the occurrence of that precipitation is immensely influenced by the degrees of acidity of the urine. Other things being equal, the more acid the urine the earlier is the precipitation, and the less acid the urine the longer is the precipitation postponed. An antacid effect, therefore, which is too feeble to render the urine actually alkaline, may be quite sufficient to depress its acidity to such a degree as shall postpone the time of precipitation until the urine has escaped from the kidneys, and even from the bladder."

—*British Med. Journal.*

REALISM IN ART.

HARPER'S WEEKLY, some time since, had a touching illustration of a visit by a Board of Health's physician to a poor family in a New York tenement house. But there is lacking at least one appurtenance to an examination of that kind, which even the fertile imagination of the artist did not conceive of, else the children in New York tenement houses are vastly cleaner than they are here. In the picture the doctor has his classic cheek close to the baby's naked breast; in reality he probably had a towel interposed.

DR. CUREALL.

THIS is the title, so the daily press informs us, of an automatic figure, or machine, another adaptation of the drop-a-nickel-in-the-slot craze. The "doctor" is provided with a plenteous number of small drawers or doors, situated over various anatomical regions. The plan is this: A man has an attack of colic—all doubled up; he drops the required coin in the proper slot, and there is pushed out to him a box of pills for the umbilical region. To be sure, pains may come in that vicinity from more causes than one, but what do you want for five cents—the earth?

Doubtless most people will smile in derision at the absurd pretensions of Dr. Cureall, but, indeed, this mechanical individual, with his regional pellets, is probably more likely to benefit the suffering patient than are the thousand and one patent abominations, each of which is a panacea, and of which thousands of gallons are yearly guzzled by an intelligent public.

SLIGHTLY SWEEPING.

THE medical profession is accustomed to periodical outbursts of indignation against the experiments made on various animals by eminent men of times both past and present. It is a perennial subject, to be used when interesting ephemeral topics are lacking.

One would not expect, however, to find as absurdly sweeping a statement as the following, made by so clever a man as the English writer, James Payn, in the London *Illustrated News*. He is commenting on the Brown-Séquard matter, and seems to labor under the delusion that the "elixir" is taken brutally from living animals. At any rate, he disposes of this distinguished physiologist, *et hoc genus omne*, by one of his carelessly sweeping statements: "As a matter of fact, they benefit nobody; unlike those military adventurers, who wade through slaughter to a throne, they carry on their filthy and cruel experiments, only to become quacks at last."

TOO CAREFUL.

THERE is a possibility of being dangerously careful of one's ease. This is illustrated by the late incident in a Bath, Me., restaurant, where the boarders, fearing that the disease with which a waitress was affected might lead to some unpleasant quarantine if a physician were called, objected to having one.

The waitress got well and resumed her work, at the same time disseminating among the one hundred and thirty-five boarders the exfoliations from a case of scarlet fever.

Should a similar occurrence ever take place, those boarders will be likely to look at least an inch or two beyond their noses.

ANOTHER case of death has occurred from the suspension treatment of locomotor ataxy—this time from Italy. The case, which occurred in the clinique of Prof. E. Galvagni, of Modena, is fully reported by Dr. Borsari in the *Riforma Medica* of July 18 and 18.

—*Medical Recorder.*

Letters to the Editor.

ACETANILIDE IN RHEUMATISM.

THE following personal experience may prove of service: May 12 I was attacked, after being up all night and getting chilled, with a stiffness in the torsal bones of both feet, which passed off after exercising. The next morning it was the same, and the next. It gradually passed off, and on the 18th I went "a fishing," tramped all day, but did not get my feet wet. Ditto the 19th. On the morning of the 20th, however, I found I was in for an attack of subacute rheumatism. The temperature and pulse were not high, 101° and 110 respectively. Joints of feet moderately swollen, and exquisitely painful and tender to the touch. The affection shifted from one joint, or set of joints, to another about once every twenty-four hours.

Salicylic acid and salicylate of soda were used faithfully, but without benefit, until finally my stomach rejected them. I received no benefit from either cimicifuga, bryonia, colchicum, or opium, this last giving me a distressing cramping pain in the stomach. Finally, I began taking five grains of antifebrin (acetanilide) every two hours, with the idea of getting some relief from the pain.

It did ease my pain, reduced my fever, and cured my rheumatism, so that three weeks from taking to the bed, and five days from the first dose of the remedy, I was able to go out. I have since attended to my practice, and although I have been caught out in a rainstorm once or twice, have had no return save some soreness and stiffness at night and in the morning, which a few doses of antifebrin (five grains) soon relieves.

Of course, I did not continue taking the five grains every two hours, but for a couple of days after that I widened the interval with every dose, until I was only using one dose a day.

Like every remedy powerful for good, it may also prove powerful for evil if misused, and I think it would be better not to give it at all to children until better known and understood. Where an antipyretic is required for a child under ten years of age I give antipyrin, which works well in doses of one-half grain at one year up to from two to three at ten years. In fact, it may be adopted as a general rule of dosage with both adults and children. "Don't give large doses; give small doses, and often."

I have treated quite a large number of cases of follicular tonsillitis this summer, and have met with unusually good results from the following course of treatment: If seen soon enough, say within thirty-six hours from the first soreness of the throat, tr. guaiac gtt. xx, every hour or two, in milk. It will usually cut short the attack. If the guaiac is insufficient, if not seen within the prescribed time, or if the patient is a child, I use hydrarg. biniod. in one-one-hundredth-of-a-grain doses every hour. Fraser's tablets, or a trituration with sugar and milk, is a convenient way of administering the medicine. It is a pleasant and sure method of treatment, and the little folks like their medicine.

If I find ulceration or patches of membrane on the tonsils, I use the corrosive sublimate in hundredth-grain doses hourly, finely powdered boracic acid in alternation with iron and glycerin, locally, and plenty of milk punch. If genuine diphtheria occurs, add the lime-water spray with oil encalyptus to the above, and you will meet with more than the average amount of success. WM. C. WOOD, M.D.

GLOVERSVILLE, N. Y.

PRECAUTIONS IN VACCINATING.

ORDINARILY in vaccinating from arm to arm the physician inquires into the health and parentage of the child from whom he takes the pus. This has not been my custom. I vaccinated here some years for the city, having brought to me every Saturday what new subject the police could find, together with the children vaccinated the Saturday previous. In selecting pus from the arms presented I made no inquiry into the health or history of the child, but directed my attention solely to the character of the sore. If it were a typical vaccine pustule I did not hesitate to inoculate from it, however tainted the child might be. On the other hand, I would refuse pus from a child both healthy and of healthy parentage if the sore were at all abnormal in appearance. In this way I vaccinated through several seasons without getting a bad arm and with the best preventive results. Smallpox has repeatedly devastated neighboring haciendas, and villages where vaccination is not practised, but though sporadic cases have occurred here, the disease, for want of subjects, has never become epidemic.

The immunity from bad sores is the more striking, in view of the fact that the majority of Mexican children of the lower class have marked hereditary taints.

I think that bad results from using human virus have been due to the error in attending to the health of the person instead of the health of the pustule. If we plant melons and gourds in the same patch, and continue to plant, using seed from the melon vines without attending to the character of the fruit, in course of time we will get nothing but hybrids. But if we select seed always from melons of the best quality, we can, for an indefinite time, reproduce superior fruit, even under such adverse circumstances. Similarly, if we select virus only from large typical pustules, we can vaccinate indefinitely from arm to arm with good preventive, and without fear of septic results. CHAS. FARVER.

SANTA ROSALIA, MEXICO.

Book Reviews.

OUTLINES OF THE CLINICAL CHEMISTRY OF URINE. By C. A. MACMUNN, M.A., M.D. (Dublin), with sixty-four woodcuts and plate of spectra. Cloth, pp. 254. Philadelphia: P. Blakiston, Son & Co., 1889.

This is a commendable book upon urinary analysis, and though the literature upon this subject is becoming rapidly voluminous, each new work presents some advantages beside its faults over all that has been issued before. The author makes free use of the larger authorities, and where there is more than one view to be taken in regard to the question in hand, he presents each side and leaves the reader to judge largely for himself. The arrangement of the matter is almost identical with that of Tyson's "Practical Examination of Urine," though its style is rather more attractive and elegant. Part I is devoted to the normal urine, its secretion, and constituents, and methods for examining the same. The testing for urohæmatoporphyrin, a pigment discovered and named by the author, receives considerable space, as would naturally be expected. Part II contains an account of the tests for the abnormal constituents of the urine. The timeliness of the work is well shown in the introduction of the latest tests for sugar by phenyl-hydrazine and safranine. Part III is a fairly illustrated section upon urinary deposits and calculi. Two appendices are added, the first containg a list of reagents and apparatus needful, and the second the explanation of some terms used in volumetric analysis, tubes, etc. The chief faults that we have to find are simply that the table of spectra is not colored and that a little more space has not been given to the principle diseases in which the tests for abnormal constituents in the urine are to be made. It is time now that a chemical work upon urinary analysis to be of special practical value should be made a part of a larger work upon general diseases; unless it is so its chief value is for the chemist and laboratory specialist only.

ON DISORDERED DIGESTION AND DYSPEPSIA. By FRANK WOODBURY, A.M., M.D., Fellow of the College of Physicians of Philadelphia, Honorary Professor of Clinical Medicine in the Medico-Chirurgical College of Philadelphia, etc. Price in paper 25 cents, in cloth 50 cents, pp. 82. Detroit: George S. Davis, 1889.

This is one of the numbers of that excellent series of medical monographs known as the Physicians' Leisure Library. The author has made a close study of digestion and its disorders. From the results of his own experiments and an extensive survey of the literature of the subject, he is in a position to assert that which is well founded and practically useful. The introduction devoted to a general exposé of the subject of digestion is followed by a highly interesting section in digestion and its disorders in man. The attention given to the rôle of microörganisms in the alimentary canal under different conditions shows that the writer is abreast of the times, and recognizes without being betrayed by mere theory the value of the recent advances made in our knowledge of the chemistry of the digestive process. Symptoms and forms of dyspepsia, and the treatment of dyspepsia, are the two succeeding sections. The last section on dietetic hints for dyspepsia will be found especially practical. The formulæ and differential diagnostic tables add very materially to the usefulness of the book.

DR. JOHN T. BANKS, of Dublin, has just received the KnightCommandership of the Bath, Civil Division, and will hereafter be known as Sir John Banks, K.C.B.

Pamphlets.

Fifteen Cases of Hydrothorax. Fifth Series. By F. Peyre Porcher, M.D., Professor of Mathematics, Medicine, and Therapeutics, Medical College State of South Carolina. From "Transactions South Carolina Medical Association," May, 1889. Reprinted from the New Orleans *Med. and Surg. Jour.*, June, 1889.

In the preceding series of cases of hydrothorax the author restricted himself to the consideration of those in which paracentesis of the pleural cavity, the lungs, or the pericardial sac was employed. In the present series of cases he undertakes to demonstrate the unsuspected frequency of pleurisies, with effusion in this country. The paper is practical and highly interesting.

The Medical Digest.

Ozæna Vera.—Ozæna vera has nothing in common with syphilis, tuberculosis, etc.; but, on the contrary, generally develops from a simple chronic catarrh, more frequently in young persons and in women. An examination of the nose in these cases reveals a peculiar atrophic condition of the mucous membrane, which is pale, thin, and shining, and of tendinous appearance, instead of bluish-red and velvety. Discolored, greenish, glutinous crusts and scabs of penetrating fætor adhere to the conchæ, which form only small flat plates. All this tends to make the nasal cavity appear more roomy than normal. Some look upon fatty degeneration of the tubercular and acinous glands as the cause of this condition. In all such cases the ciliated epithelium of the nose becomes changed into pavement epithelium; in other words, it becomes "epidermoidized," and the throwing off of the superfluous and softened pavement epithelium gives rise to the well-known foul odor.—*Volkmann's Klin. Vorträge*, 340.—*Journal of the Respiratory Organs.*

Pilocarpine in the Convulsive Attacks of Hystero-epilepsy and Maniacal Excitement.—In the *Journal of Nervous and Mental Diseases*, Dr. Samuel B. Lyon reports the case of a married woman, aged thirty, in whom the convulsive seizure had the characteristics of hystero-epileptic attacks, who was relieved by a hypodermic injection of one-eighth grain of muriate of pilocarpine over the left ovary. Her temperature, which had been 103⅖°, fell to 101⅕°. The convulsive movement ceased, consciousness gradually returned, and a quiet sleep followed. In this case inhalations of amyl nitrite and ether had only temporarily quieted the spasmodic condition.

—*Therapeutic Gazette.*

A Case of Bronchial Calculus.—Dr. Pasquale Moscato relates (*Gazzetta degli Ospitali*, July 31, 1889) a case in which calculi were coughed up, not from the lungs, but from the bronchial tubes. The patient, a healthy woman, aged thirty, with an excellent family history, during her first pregnancy suffered from dyspnœa and cough, and the sputa were streaked with blood. These symptoms disappeared after delivery, but four years later, the patient being again pregnant, they returned; this time a calculus of about the size of a small shot, yellowish-white in color, and flattened in shape, was expelled in coughing. A second calculus was expectorated in the following year, when the patient was not pregnant, and a third the year after (1885) in the first months of another pregnancy. During 1886 there was no repetition of the occurrence, and the woman remained perfectly well, with the exception of slight bronchial catarrh. In April, 1887, and May, 1888, two other calculi were expelled. On each occasion the event occurred in the course of bronchial catarrh, and was preceded by pain in the left lung, especially severe in the supra-cardiac region. After the expulsion of the calculus this pain gradually disappeared. The calculus expelled in May, 1888, was larger than the previous ones, and of irregular shape, with branch-like processes. The woman suffered at the time from fever of intermittent type, and the bronchial catarrh was accompanied by hæmoptysis. On auscultation, both pulmonary apices seemed to be quite healthy, and there was no dulness over the area of either lung. On the left side, outside the mammary region, crepitant râles were audible, but there was absolutely no physical sign of a cavity. Dr. Moscato believes that the expectorated substances are genuine calculi, not pellets of inspissated mucus, or calcareous concretions. They were analyzed by Dr. Russo Giliberti, Professor of Pathology in the University of Palermo, and found to contain traces of albuminoid material, with chloride of lime, chloride of sodium, and chloride of magnesium. Neither uric acid nor oxalate of lime was present, nor were there any carbonates, phosphates, or sulphates. The absence of oxalate of lime differentiated the calculi in this case from those occasionally expelled by patients suffering from asthma. Dr. Moscato thinks the absence of fever and of all physical signs pointing to disease of the lung, together with the small quantity of blood expectorated, negatives the possibility of the calculi having come from the lungs. He maintains that they probably originated in the bronchial mucous membrane, as they are known to do in tne lingual, salivary, and other glands, and that the streaks of blood in the sputa were due to the detachment of the calculi. Dr. Moscato believes his case to be unique in medical literature up to the present.

HYDROTHERAPEUTICS FOR DYSPEPSIA.—Dr. Chas. Kevin, in a paper read before the Ulster Medical Society, says he has tried about a dozen cases of painful dyspepsia with what is called the "hot pad" and "binder." It is made up of three parts—a pad (fourply of swansdown) about twelve inches by six inches; a roller two yards long, half swansdown and the other half mackintosh cloth; and one and one-half yards of a flannel binder. The pad is put into boiling water and wrung out. It is then put over the abdomen at bedtime, covered with the cotton and waterproof binder; and over all the flannel binder is placed. In the morning all is removed, the abdomen is sponged with cold water and rubbed with a rough towel, the flannel binder is then put on and worn throughout the day. Where much pain is complained of, the whole apparatus may be worn constantly. He thinks the beneficial effects are due to the fact that more blood is brought to the parts requiring it; spasm is relieved, and support is given to the abdominal muscles. He finds in cases where he has ordered it that it relieves flatulency, pain, constipation, and distension. It is also useful in insomnia, and cleans the tongue when it is coated.

—*Dub. Journ. of Med. Sciences—The Practitioner.*

ON CREOLINE IN DYSENTERY.—N. P. Sossowsky (*Vratsch*, No. 14, 1889) used in sixteen cases of dysentery clysters of a solution of ½ per cent. of creoline. The clyster (from 2 to 3 and even 3½ litres), was generally given twice a day, sometime three and even four times. No disagreeable secondary symptoms. The patients did not complain of either smarting or abdominal pain. The results obtained were as follows: In two cases the disease was broken up after two injections; in nine cases the bloody stools disappeared on the third day, in two on the fifth, in one on the sixth, and in another on the ninth. In the last case the appearance of putrid matter in the stools was not checked, but the patient recovered nevertheless. Not one of these patients died, although there were a great many cases with fatal termination reported in the city. From these observations the author draws the following conclusions:

1. Clysters of a ½ per cent. solution of creoline possesses antiseptic qualities and seem to be less dangerous and toxic than the clysters of sublimate or phenol.

2. Clysters of creoline check the blood without irritating the intestinal channels.

3. Cases acute from the beginning, with frequent tenesmus and copious bloody stools, take a more favorable course and are cured more rapidly than cases insidious at the beginning, characterized by catarrhal stools.

4. In cases where the creoline clysters do not stop the development of the intestinal catarrh, clysters of tepid water and subsequently of a solution of acetate of lead, ½ per cent., or of tannin of 1–2 per cent., should be prescribed; at the same time a decoction of the bark of quinquina should be taken internally with sulphate of soda.

The author has successfully used the same treatment in two children, one eleven and the other nine months old. Dr. Kolokoloff has prescribed creoline clysters (1 per cent.) in twelve cases of dysentery; all the patients recovered without showing at any time alarming secondary symptoms.—*Les Nouveaux Rèmedes*, No. 11, 1889.—*Journal of Med. Asso.*

HYSTERECTOMY FOR FIBROIDS IN VIENNA.—Prof. Albert has published, in the *Wiener Med. Wochenschrift*, II, 1889, a paper on ten successful cases of abdominal section for myoma of the uterus. In all, the extra-peritoneal method of treating the stump was adopted. The elastic ligature was used in order to prevent hemorrhage during the enucleation of the fibroid and the amputation of the uterus, the stump being fixed with pins. In fact, the operation was performed in the manner practised by Drs. Keith and Bantock in this country. In one case an abscess in Douglas's pouch was laid open during the operation. The abscess was drained through the posterior vaginal fornix, the tube being removed on the fourteenth day. In another, Prof. Albert found a pancreatic cyst in close proximity to the uterine myoma, which was very large, and removed both. This remarkable case will, the author informed his readers, be published in full. In one (and apparently in only one) of the ten cases a myoma had to be shelled out of the hyoid ligament. The posterior layer of the ligament was sewn to the abdominal incision, and the cavity left between the layers was stuffed with iodoform gauze. Prof. Albert rejected the use of sponges for cleaning the peritoneum, and attributed his success in no small degree to this new departure. Our readers are aware that Dr. Keith, a successful operator, published a paper in the Journal of June 8, wherein he advocated electricity as a safer and more justifiable proceeding in cases of fibroid than hysterectomy. Opinion is still much divided on this question.

—*British Med. Journal.*

LABOR COMPLICATED BY THE ADMINISTRATION OF ONE-FIFTH OF A GRAIN OF STRYCHNINE.—Avrard (*Bulletin de la Société Obstétricale de Paris*, No. 6, 1889) reports the case of a primipara to whom a midwife had given strychnine aggregating one-fifth of a grain to secure vigorous pains. This result not following, a physician was called. The fœtus was found to be in cephalic presentation; dilatation of the os and cervix was complete. Traction with the forceps failing, the uterus was found tetanized and very hard. A hot bath was given, belladonna ointment was applied to the os, and under chloroform the head was brought to the pelvic floor by forceps and delivered. As the cord was about the neck, the attempt to deliver the shoulders rapidly was made, but failed. Rotation was very difficult from the uterine rigidity; the child was stillborn; the mother recovered without complications. None of the usual constitutional effects of the drug were observed; pains in the legs and convulsive movements were present. The patient's subsequent labor was marked by uterine inertia requiring forceps.

LIGHT IN THE SICK-ROOM.—Still a custom prevails, despite all our sanitary teachings, that the occupant of the sick-room in the private house should be kept at all hours in a darkened room. Not one time in ten do we enter a sick-room in the daytime to find it blessed with the light of the sun. Almost invariably, before we can get a look at the face of the patient, we are obliged to request that the blinds may be drawn up, in order that the rays of a much greater healer than the most able physician can ever hope to be may be admitted. Too often the compliance with this request reveals a condition of room which, in a state of darkness, is almost inevitably one of disorder everywhere; foods, medicines, furniture, bedding misplaced; dust and stray leavings in all directions.

In brief, there is nothing so bad as a dark sick-room; it is as if the attendants were anticipating the death of the patient; and, if the reason for it be asked, the answer is as inconsistent as the act. The reason usually offered is that the patient cannot bear the light; as though the light could not be cut off from the patient by a curtain or screen, and as though to darken one part of the room it were necessary to darken the whole of it. The real reason is an old superstitious practice, which once prevailed so intensely that the sick, suffering from the most terrible diseases, smallpox, for instance, were shut up in darkness, their beds surrounded with red curtains, during the whole of their illness. The red curtains are now pretty nearly given up, but the darkness is still accredited with some mysterious curative virtue.

A more injurious practice really could not be maintained than that of darkness in the sick-room. It is not only that dirt and disorder are results of darkness, a great remedy is lost. Sunlight is the remedy lost, and the loss is momentous. Sunlight diffused through a room warms and clarifies the air. It has a direct influence on the minute organic poisons, a distinctive influence which is most precious, and it has a cheerful effect upon the mind. The sick should never be gloomy, and in the presence of the light the shadows of gloom fly away. Happily, the hospital ward, notwithstanding its many defects, and it has many, is so far favored that it is blessed with the light of the sun, whenever the sun shines. In private practice the same remedy ought to be extended to the patients of the household, and the first words of the physician or surgeon on entering the dark sick-room should be the dying words of Goethe, "More light, more light!"
—*B. W. Richardson, M.D., in Scientific American.*

DIPHTHERITIC GASTRITIS OR GASTRIC DIPHTHERIA.—Talfourd Jones (*Brit. Med. Jour.*, 1889, II, 880) reports a case of this very rare affection. The patient, a child of two years and ten months, developed difficulty in swallowing on the third day of the disease; on the sixth, she vomited several times; on the seventh, there was difficulty in breathing and frequent vomiting, the ejecta consisting of a little blood and some dark red pieces of a membranous character. Death occurred on the following day. The autopsy revealed a widespread membranous exudation of the pharynx and adjacent parts, the posterior nares, and the larynx down to the cricoid cartilage, where it abruptly ceased. The œsophagus was quite normal in every respect. The stomach had a soft, doughy consistence, and, when opened, presented an irregular, dark, reddish-brown appearance, with a slightly olive-green tint. This was found to be the surface of a continuous membrane lining the whole of the stomach. It varied in thickness, averaging one-twelfth of an inch, but being thickest over the rugæ. It was adherent to the mucous membrane, but was easily separated and peeled off, and then exhibited on its under surface the imprint of the markings of the mucous membrane. Except in thickness and in its dark red color it differed little from the exudation in the pharynx.

The rugæ of the mucous membrane were of a black-red hue and studded with a dark red punctiform injection. The mucous lining between the rugæ was of a much lighter color. The intestines were healthy.

Under the microscope the exudation from the stomach presented an irregular fibrillated appearance with numerous red blood-cells and leucocytes.

American Jour. of Med. Sci.

CONGENITAL STENOSIS OF THE PYLORUS.—Dr. W. K. Peden records an example of this exceedingly rare affection. The infant, who at birth appeared healthy and well developed, commenced vomiting three days afterwards, and continued to do so throughout the remainder of his life, which terminated when he was three months old. Neither medicines nor alterations in the diet exerted any beneficial influence. No tumor could be felt during life, and there was no evident dilatation of the stomach. The following was the condition found on post-mortem examination. Extending from the pylorus into the stomach, exactly implicating the rounded straight *portio pylorica* of the infantile stomach, was a stiff sausage-shaped thickening of the part, reducing the lumen of the canal to about 5 mm. Section of the stomach along the greater curvature showed the hypertrophied portion beginning gradually in the stomach walls and ending apruptly in a ball-shaped knob which projected freely into the duodenum. The lumen of the canal was still further narrowed by two longitudinal crest-like projections extending along the whole length of the hypertrophied portion. The cardiac portion of the stomach was covered with a mucous coating, and hardening reagents revealed a thin grayish reticulated exudation covering the pyloric tract. The exudation consisted of cells derived from the pyloric gland cells. The submucosa was enormously thickened; and the circular muscular fibers showed a marked degree of hypertrophy. The outer muscular coat and the peritoneum were normal.

—*Glasgow Med. Journ., The Practitioner.*

ERYSIPELAS TREATED WITH PURE ALCOHOL.—M. C. Dr. Behrend, physician of the prison of Sagaw, reports, in the *Berlin Klinische Woch.*, the cure of cases of erysipelas, in three or five days, by means of lavings repeated three times a day of the affected parts with alcohol at 90°. This treatment checked the disease at once, and the patients were not confined to bed.—*Revue de Thér.*

Medical News and Miscellany.

TYPHUS FEVER is epidemic in Toluca, Mexico.

A DEATH from Asiatic cholera is reported to have occurred in Little Sandusky, Ohio.

LANCASTER is greatly in need of an ambulance, and has a $100 fund for that purpose.

DR. ANDREW BEDFORD, died at Waverley, Luzerne County, on Tuesday night, in his ninetieth year.

THE Atlanta *Medical and Surgical Journal* is to be under the management hereafter of Dr. F W. McRae.

THE death is announced of Dr. Thomas King Chambers, Honorary Physician to the Prince of Wales.

FATHER DAMIEN (known as the leper martyr), it is now stated, attributed his leprosy to the inoculation by flies of an abrasion on his scalp.

THE opposition of the Swiss government towards the English physicians stopping or traveling in Switzerland is producing quite a stir in England.

WHILE suffering from typhoid fever Alfred Jones, twenty-three years old, jumped from a third-story window of his residence, and was seriously injured.

THE annual meeting of the American Academy, for 1889, will be held at Chicago, Ill., November 13 and 14, being postponed to that date by authority of the Council.

IT is said that Philadelphia will contain a larger number of medical students than ever this year, Jefferson College, as usually, having the longest list of matriculates.

DR. J. R. PARTENHEIMER is lying seriously ill at his home, 633 North Eleventh Street, from injuries received in an accident that occurred while on his way to visit a patient at Ardmore.

GOVERNOR BEAVER has ordered Mr. Hamilton to complete the work of cleansing out all cellars and places as quickly as possible in Johnstown, that are pronounced in a bad sanitary condition.

EIGHTEEN cases of typhoid fever in this city are said to have been traced to the use of well-water. A great many other cases are ascribed to Delaware water, which everybody agrees should not be used.

MR. Z. PRITCHETT, of Lake's District, Dorchester County, is a rare specimen of humanity, in his anatomical construction. He is suffering with pulmonary diseases, and on the recommendation of Dr. Jones, his home physician, came to Salisbury to be examined by Dr. John S. Fulton. During the physical examination Dr. Fulton accidently discovered that the man's heart was located on the right side of his body. This greatly interested the doctor, but as his patient did not consult him on this point he did not feel at liberty to make a minute investigation. It was not, therefore, ascertained whether the other organs were transposed. The case is one of peculiar interest to the profession, since it is so rare that less than two hundred such cases are on record.—*Record.*

COMMON soap, given as soon as possible and continued as long as there are any toxic symptoms, is an efficient antidote for carbolic acid poisoning, says the *Rev. de Therap. Med. Chir.*

THE PARIS INTERNATIONAL CONGRESS OF DERMATOLOGY AND SYPHILOGRAPHY.—Dr. A. R. Robinson, of New York, has been appointed by the committee on organization to open a discussion on the subject of lichen.

THE expiration of the term of Dr. Kirby at the University Hospital, promotes Dr. Wood to be senior resident; Dr. Easter, senior surgeon; Dr. Provost, junior surgeon; Dr. Kneas, senior medical, and Dr. Aldrich, junior medical.

MRS. MARIA O. BEYAR, Matron of the Pennsylvania Hospital, department for insane females, has tendered her resignation, to take effect November 1, impaired health having disqualified her for longer discharging the duties of the post.—*Ledger.*

A MEETING was held at noon, September 6, at the office of Charles B. Baeder, 730 Market Street, of the Committee having in charge the presentation of a free bed in the Polyclinic Hospital to be perpetually endowed as a testimonial to Dr. Richard J. Levis.

PARAPHENACETINE. — Prof. Dujardin-Beaumetz states that this drug does not produce cyanosis and eruptions like antipyrin and acetanilid. It can be given in doses of two grammes without danger of intoxication, which is due probably to the fact of its insolubility.

DR. EPHRAIM CUTTER, of New York, at the banquet of the British Medical Association, responded to the toast, "Our Guests," for the Americans present. Dr. Cutter also read on "Galvanism of Uterine Fibroids," closing the discussion on the same, and demonstrated on the screen his lantern slides of the micro-photographs of healthy and diseased blood, and of the sputum, urine, fæces, and skin, which he and Dr. Harriman, of Boston, took, in 1876, with Tolles' superb $\frac{1}{4}$, $\frac{1}{10}$, $\frac{1}{16}$, $\frac{1}{50}$, and $\frac{1}{75}$ inch objectives.

"THE members of the medical profession in Alabama, Georgia, and Tennessee are requested to meet in Chattanooga on the third Tuesday in October, for the purpose of forming a tri-State Medical Association. All will be admitted to the meeting of the Association, but the membership will be restricted to graduates of regular medical colleges in good standing."

Signed by committees from Jackson County, Alabama, Medical Society; Chattanooga, Tennessee, Medical Society; Cleveland, Tennessee, Medical Society; Cartersville, Georgia, Medical Society; Dalton, Georgia, Medical Society.

It is hoped that there will be a general turnout of the profession. Papers of interest have been promised by prominent men. The session will continue two days.

Another circular will be issued in due time announcing the titles and authors of papers.

FRANK TRESTER SMITH, M.D.,
Secretary of Committee.

One of the New York papers having offered a prize to the Metropolitan mother who had successfully reared the largest number of boys and girls, it was carried off by the mother of fifteen children, all living, the youngest being five years of age. The father of this interesting family was one of fifteen children, some of whom have died, but the mother is one of fifteen, all of whom are living, some of them at advanced ages.

An English physician in writing about drinking water says: "If, in any hotel or summer resort to which these lines may come, there should occur a single case of typhoid fever or diphtheria, test the drinking water or have it done at once. A few pence will buy an ounce of saturated solution of permanganate of potash at a chemist's. If, when a drop of this solution is added to a tumbler of water, its color changes to brown, it is unfit to drink; if it remains clear or slightly rose-colored after an hour, it is, broadly speaking, safe."

An Army Medical Board will be convened in New York City, N. Y., October 1, 1889, for the examination of such persons as may be properly invited to present themselves before it as candidates for appointment in the medical corps of the Army.

Application for an invitation should be addressed to the Secretary of War, stating date and place of birth; place and State of permanent residence, and accompanied by certificates, based on personal acquaintance, from at least two persons of repute, as to citizenship, character, and moral habits; testimonials as to professional standing, from the professors of the medical college from which the applicant graduated, are also desirable. The candidate must be between twenty-one and twenty-eight years of age, and a graduate from a regular medical college, evidence of which, his diploma, must be submitted to the Board.

Further information regarding the examinations and their nature may be obtained by addressing the Surgeon-General, U. S. Army, Washington, D. C.

Appointed Professor of Pathology.—At the last meeting of the Faculty of the Medico-Chirurgical College, Dr. Ernest Laplace was appointed Professor of Pathology. Professor Laplace is a native of New Orleans, and a graduate of the Literary Department of the Georgetown University, D. C. After several years' study in Tulane University and the Charity Hospital, he went abroad, and graduated in the "Faculté de Medicine de Paris," where he studied under Pasteur and Cornil. He afterward spent seven months in Vienna, under Billroth and Stricker, and a year in Berlin, with Koch and von Bergmann. While with Koch he discovered the superior efficiency as a germicide of acid sublimate of mercury, and of sulpho-carbolic acid as a disinfectant. After his return to New Orleans he instituted a Pasteur laboratory for the treatment of hydrophobia, and was elected Visiting-Surgeon to the Charity Hospital. At the time of his call to this city he was Professor of Physiology and Hygiene in the High School Department of the Tulane University, and Demonstrator of Microscopical Anatomy and Bacteriology in the Medical Department of the same school.

The new maternity ward of the University Hospital was opened with one patient. The building is situated on the southwest corner of the hospital grounds, is a one-story structure of Gothic architecture and contains five beds. The ward is in charge of Nurse M. Wilson, who is assisted by Miss Yost. The visiting physicians are Dr. Barton C. Hirst and Dr. Richard C. Norris.

The few statistics at hand show that the cork trade of the United States amounts to $1,700,000 to $2,000,000 per annum, which represents at least six million to eight million gross of corks. The number of hands employed is about one thousand. The importations of bark amount to about fifty thousand bales per annum, representing possibly $1,000,000 value. Cork varies in value from 2 cents per pound up to 50 cents or even $1.00 in some cases.

—*Pharmaceutical Era.*

Dr. Webster Fox, in the Journal of the Franklin Institute, maintains that the majority of blind people have lost their sight from want of proper care during infancy, and that nurses or mothers who heedlessly expose an infant's eyes to the glare of the sun for hours, may be laying the foundation of the most serious evils. He protests against permitting young children to use their eyes in study, and declares that the eye is not strong enough for school work until the age of seven to nine. Children should not be allowed to study much by artificial light before the age of ten, and books printed in small type should be absolutely prohibited in the school-room.

Lawson Tait's operation for laceration of the perineum, by splitting the recto-vaginal septum and forming flaps from it, has found much favor among gynecologists, especially among the Germans.

A recent paper (Volkmann's klin. Lectures, No. 301) by Saenger, of Leipzig, furnishes an excellent description with drawings of nineteen cases of complete as well as incomplete ruptures, in which the results were all that could be desired. The procedure appears to be a rational one, as it removes nothing from the vulva and restores the perineum to its original shape without great narrowing of the orificium vulvæ. The latter effect precludes its usefulness for restoration of prolapsus, in which trouble the old operations will be preferred.

In the London Society for Medicine and Surgery, a guest, Dr. Arnold Shetelig, declared that the presence of free crystals of uric acid in the urine points to the same form of gouty diathesis. The free uric acid differs from that combined with alkalies in the form of water, in the tendency to crystallize out of and to unite with other portions of uric acid that may be present. The author analyzed fifty-two cases, of which eight were pathological, and found 25 to 50 per cent. and over of the total uric acid in the uncombined crystalline form in patients, who, without doubt, had suffered or were then suffering from true gout. Especially important is the test for the diagnosis between true and false gout. This form of uric acid may for a time be reduced by baths alone or with alkaline water, but in most cases it will reaccumulate.

DR. DAVID T. BROWN, once a famous expert in insanity cases, but of late years following the occupation of a farmer in Illinois, has committed suicide.

PRELIMINARY PROGRAMME of the Session of the Southern Surgical and Gynæcological Association to be held in Nashville, Tenn., November 12, 13 and 14, 1889:

The President's Annual Address, Hunter McGuire, M.D., L.L.D., Richmond, Va.; Report of Gynæcological Work, with Especial Reference to Methods, R. B. Maury, M.D., Memphis, Tenn.; Direct Herniotomy, with Cases, W. O. Roberts, M.D., Louisville, Ky.; Open Abdominal Treatment, B. E. Hadra, M.D., Galveston, Texas.; The Abortive Treatment of Acute Pelvic Inflammation, Virgil O. Hardon, M.D., Atlanta, Ga.; The Importance of Early Treatment of Inflammatory Affections of the Uterus, Wm. C. Dabney, University of Virginia; The Relation of the Nerve System to Reparative Surgery, Thos. O. Summers, M.D., Jacksonville, Fla.; Concerning the Causes of Frequent Failure of Relief of Reflex Symptoms after Trachelorraphy, W. F. Hyer, M.D., Meridian, Miss.; Cranial Surgery, DeSaussure Ford, M.D., Augusta, Ga.; The treatment of Ectopic Pregnancy, W. H. Wathen, M.D., Louisville, Ky.; Laparotomy in Extra-Uterine Pregnancy, Waldo Briggs, M.D., St. Louis, Mo., Epithelioma of the Penis, with the Report of a Case, D. W. Yandell, M.D., Louisville, Ky.; Laparotomy in Intestinal Obstruction, C. Kollock, M.D., Cheraw, S. C.; An Experimental Study of Intestinal Anastomosis, John D. S. Davis, M.D., Birmingham, Ala.; Operative Interference in Ascites, Hugh M. Taylor, M.D., Richmond, Va.; Observations Pertaining to Pregnancy and Parturition, W. Duncan, M.D., Savannah, Ga.; Puerperal Convulsions, John Herbert Claiborne, M.D., Petersburg, Va.; Some Remarks upon Aneurisms, relating more especially to their Surgical Treatment, F. T. Meriwether, M.D., Asheville, N. C.; Coccygodynia and its Treatment, Hunter P. Cooper, Atlanta, Ga.; The Improved Cæsarean Section *versus* Craniotomy, W. D. Haggard, M.D., Nashville, Tenn.; Conservative Surgery in Injuries of the Foot, J. T. Wilson, M.D., Sherman, Texas; Gunshot Fractures of the Femur, John Brownrigg, M.D., Columbus, Miss.; Tropho-Neurosis as a Factor in the Phenomena of Syphilis, G. Frank Lydston, Chicago, Ill.; Trophic Changes Following Nerve Injury in Fractures, with a report of two cases, Wm. Perrin Nicholson, M.D., Atlanta, Ga.; Treatment of Malignant Diseases of the Rectum, W. T. Briggs, M.D., Nashville, Tenn.; Title of papers not determined, W. L. Robinson, M.D., Danville, Va.; W. Rogers, M.D., Memphis, Tenn.; L. S. McMurtry, M.D., Danville, Ky.; E. J. Beall, M.D., Fort Worth, Texas; E. Burke Haywood, M.D., Raleigh, N. C.; Paul B. Barringer, M.D., University of Virginia; J. F. Y. P. Paine, M.D., Galveston, Texas; The Achievements of Modern Surgery, J. Ewing Mears, M.D., Philadelphia, Pa.; The Treatment of the Pedicle in Supra-Pubic Hysterectomy, Wm. M. Polk, M.D., New York; Abdominal Surgery, Joseph Price, M.D., Philadelphia, Pa.

To Contributors and Correspondents.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer upon us a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from September 3, 1889, to September 9, 1889.

VALLUM, EDWARD P., Colonel and Surgeon; MCELDERRY, HENRY, Major and Surgeon; MATTHEWS, WASHINGTON, Major and Surgeon; MURRILL, JAMES C., Captain and Assistant-Surgeon: Will, by direction of the Secretary of War, constitute a Board of Medical Officers to meet in New York City on the 1st day of October, 1889, or as soon thereafter as practicable, for the examination of assistant-surgeons for promotion and of candidates for admission into the medical corps of the Army. The Board will be governed in its proceedings by such instructions as it may receive from the Surgeon-General. Par. 1, S. O. 203, A. G. O., September 2, 1889.

JANEWAY, JOHN H., Major and Surgeon. The leave of absence granted, with the approval of the Secretary of War, in S. O. 52, July 29, 1889, Division of the Pacific, is extended two months. Par. 1, S. O. 206, A. G. O., September 5, 1889.

CLEARY, P. J. A., Major and Surgeon. Is hereby granted leave of absence, on surgeon's certificate of disability, for two months. S. O. 59, Headquarters Division of the Pacific, San Francisco, Cal., August 27, 1889.

EWING, CHARLES B., Captain and Assistant-Surgeon. Is granted leave of absence for twenty-one days, to commence on or about September 21, 1889, provided that at that time the post surgeon now on leave has returned to duty. Par. 5, S. O. 201, Headquarters Division of the Atlantic, Governor's Island, N. Y., September, 4, 1889.

The garrisons of Fort Laramie, Wyoming, Fort Hays, Kansas, and Fort Lyon, Colorado, by S. O. 69, A. G. O., August 31, 1889, will be withdrawn, and the posts named will be abandoned as soon as it can be done with due regard to economy.

Changes in the Medical Corps of the United States Navy for the week ending September 7, 1889.

NASH, F. S., Passed Assistant-Surgeon. Detached from the "Dale," and ordered to duty in the Bureau of Medicine and Surgery.

RUSSELL, A. C. H., Passed Assistant-Surgeon Ordered to Naval Hospital, Yokohama, per steamer of September 28.

HALL, C. H. H., Passed Assistant-Surgeon. Detached from Naval Hospital, Yokohama, on reporting of relief, and return home.

WHITE, S. S., Assistant-Surgeon. Detached from Naval Hospital, N. Y., and ordered to the "Minnesota."

STONE, E. P., Assistant-Surgeon. Detached from the "Minnesota," and wait orders.

BRYANT, P. H., Assistant-Surgeon. Detached from the "Ajax," and ordered to Naval Hospital, Norfolk, Va.

WENTWORTH, A. R., Assistant-Surgeon. Detached from Naval Hospital, Norfolk, Va., and wait orders.

Medical Index.

We purpose in this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

A plea for the inebriate, E. J. Kempf, M.D., Jasper, Ind. N. C. Med. Journal, August, 1889.

Anatomie Pathologique du Glaucome, J. Fontan, Recueil d'Ophthalmologie, Aout, 1889.

Antiseptic principles, some further applications of, to midwifery practice, Cullingsworth. Med. Press and Circular, August 21, 1889.

Address in medicine, Jackson. British Medical Journal, August 17, 1889.

Albuminuria, on the prognosis of cases of, with special reference to life insurance, Pavy. The Lancet, August 24, 1889.

Asthma, some observations on the causation and treatment of, Robinson. Medical News, August 31, 1889.

Apostoli's treatment, Black. Maritime Med. News, September, 1889.

Acute infectious fevers, with especial reference to differential diagnosis, Phillips. Kansas Med. Journal, Sept., 1889.

Aus der Medicinischen Poliklinik zu Bonn, Hagemann. Berliner Klinische Wochenschrift, August19, 1889.

Bradshawe lecture, the, on the distribution and duration of visceral new growths, delivered at the Royal College of Physicians of London, Moore. The Lancet, Aug. 31, 1889.

Bad air as a disease producer, De Armond. Med. Bulletin, September, 1899.

Cortical epilepsy—clinical lecture, David Inglis, M.D. Canada Lancet, September, 1889.

Chorea Erwaschsener mit Endocarditis recurrens, Grosse. Berliner Klinische Wochenschrift, August 19, 1889.

Chirurgie chez les Indiens, La Marais. L'Anneé Medicale, Aout 15, 1889.

Carbolic or phenic acid, Branch. Medical World, August, 1889.

Diplopie monoculaire, Brunschwig. Recueil d'Ophthalmologie, Aout, 1889.

Die abgestufte Reizung des Herzvagus, Hüfler. Centralblatt für die Medicinischen Wissenschaften, August 24, 1889.

Die Behandlung des Kenchhustens mit Antipyrin, Sonnenberger. Deutsche Medizinal-Zeitung, August 26, 1889.

Die Therapie der Augenmuskellähmungen, Mauthner. Wiener Medizinische Blätter, August 22, 1889.

Drainage of the bladder, a new method of, after suprapubic cystotomy, Fowler. N. Y. Med. Journal, Sept, 7, 1889.

Ein besonderer congenitaler Choanenverschluss, Onodi. Berliner Klinische Wochenschrift, August 19, 1889.

Ein Fall Creolin vergeftung ferin Menschen, Friede von Ackeren. Berliner Klinische Wochenschrift, August 12, 1889.

Ein Weiterer Beitiagzur Kenntniss der infektiösen Hühnerenteritis, Klein. Centralblatt für Bakteriologie und Parositerkunde, August 24, 1889.

Epilepsy, the surgical treatment of, Alexander. Med. Press and Circular, August 21, 1889.

Ectopic pregnancy and pelvic hæmatocele, the pathology of. The American Journal of Obstetrics and Diseases of Women and Children, August, 1889.

Electro-magnet in ophthalmology, notes on the, with a report of nine cases, Briggs. Occidental Med. Times, Aug., 1889.

Eczema scrotalis, Murich. Medical World, 1889.

Employment of alcohol in medicine, a contribution towards the discussion on the, Bartley. The Lancet, August 31, 1889.

Foreign Bodies in the larynx, with a report of the successful removal of fish bones from the larynx of an infant, Waxham. American Practitioner., September, 1889.

Fractures of the neck of the femur, the treatment of, by immediate reduction and permanent fixation, Senn. Jour. Amer. Med. Asso., August 3, 1889.

Fracture of the thigh, a case of, with non-union, Manley. Boston Med. and Surg. Jour., August 29, 1889.

Fulminating pyohæmothorax in an infant aged eight months, Thoney. The Lancet, August 31, 1889.

Heart tonics, F. C. Heath, M.D. American Lancet, September, 1889.

Hepatitis and hepatic abscess; their etiology, diagnosis, and treatment, G. Harrison Young, L.K.Q., C.P.I., etc. Medical Press and Circular, August 28, 1889.

Hæmorrhagic Fever, Lamb. Med. Bulletin, Sept., 1889.

Hypnotism and suggestion, cases treated by, Ireckey. The Lancet, August 24, 1889.

Intra-thoracic growths developing from the thyroid gland, Ashe. Med. News, September 7, 1889.

Joint scraping, on, with table of cases treated, Lediard. The Lancet, August 31, 1889.

Lumbago, Evan Hadley, M.D., Indianapolis. Indiana Med. Journal, September, 1889.

L'Honnêteté de Pomée de Villeneuve. Journal de Hygiéne, Jeudi, Aout 29, 1889.

Leprosy, a study on, Sandreczki Atkinson. The Lancet, August 31, 1889.

La Mort subite dans les maladies graves du larynx, Picards Botey. Revue de Laryngologie d'Otologie et de Rhinologie, September 1, 1889.

Modern Sanitary Conditions, Geo. E. Waring, Jr., Newport, R. I. Jour. Amer. Med. Asso., September 7, 1889.

Medical officers of health; their training and the conditions on which they should hold office. An address by E. Ballard, M.D., F.R.S. British Medical Journal, August 31, 1889.

Milk sickness, Fuller. American Practitioner, Sept. 1889.

Modern sanitary conditions, Waring. Jour. Amer. Med. Asso., September 7, 1889.

Music and its therapeutic value, the influence of, Wernnier. N. Y. Med. Journal, September 1, 1889.

Medicine and medical education, a cursory review of the progress of, Wheelhouse. Med. Press and Circular, August 21, 1889.

Nervous System, on the comparative study of diseases of the, Jackson. Medical Record, August 31, 1889.

On placenta prævia, J. Braxton Hicks, M.D., F.R.S., F.R.C.P., etc. Medical Press and Circular, August 28, 1889.

On the treatment of cancer of the rectum, T. R. Jessop, F.R.C.S. *Ibid.*

Ornells est la Meilleure Methode d'Extraction de la Cataracte, Aguilar Blanch. Recueil d'Ophthalmologie, Aout, 1889.

Olfactory nerve, the; its quantitative and qualitative tests, and its physiological importance, its intracranial course and diseases, Dana. N. Y. Med. Journal, Sept. 7, 1889.

Physiological value of meat food for invalids, and waste in methods of prepa ation, Chas. Moore Jessop, M.R.C.P., Lond. British Med Journal, August 31, 1889.

President's address delivered at the fifty-seventh annual meeting of the British Medical Association, Wheelhouse. British Medical Journal, August 17, 1889.

Pathologie de la tuberculose, Germain Sée. La France Médicale Jeudi, Aout 22, 1889.

Progress in education, signs of, Cincinnati Lancet-Clinic, August 31, 1889.

Pharmaceutic instruction in different countries. Pacific Record of Medicine and Surgery, August 15, 1889.

Recent advances in the treatment of diseases of the skin, L. Duncan Bulkley, M.D., New York. Jour. Amer. Med. Asso., September 7, 1889.

Railway surgery, L. E. Russel, M.D. Journal of the Nat. Asso. of Railway Surgeons, August, 1889.

Salines in peritonitis, G. W. Miltenberger, M.D. Maryland Medical Journal, September 7, 1889.

Sur l'Hygrométricite de la Substance Solide du Corps Vitré, E. Haghe. Recueil d'Ophthalmologie, Aout, 1889.

Vaginal hysterectomy with abdomina ovariotomy, A. Groves, M.D. Canada Lancet, September, 1889.

Wider die Lehre von der Selbstinfektion, Wilhelm Thorn, Magdeburg. Berliner Klinische Wochenschrift, August 19, 1889.

SURGICAL DRESSINGS.

(Read at the annual meeting of the New York State Medical Association, Third District Branch.)

BY CHAS. W. BROWN, M.D.,
ELMIRA, N. Y.

THE materials used in the performance of a surgical operation and its after-treatment, form such an important part of the surgeon's outfit, that it may be of interest to give a little time to the apparatus needed, and methods of dressing wounds, in the practice of to-day. I shall not attempt to speak of dressings as applied to all forms of surgical procedures, but will confine my remarks principally to the discussion of practical methods of dressing recent wounds, and the after-treatment of amputations.

Surgical dressings should be applied for the purpose, first, to restore injured parts as nearly as possible to their normal position, with as near perfect coaptation as possible; second, to maintain such coaptation with as little injury to the tissues as the circumstances in each individual case will allow; with dressings and appliances that are not more bulky and cumbersome than are necessary to fulfil the foregoing requirements; they should be left in place as long as they answer the purpose for which they were applied.

I shall not undertake to enumerate the thousands of applications and dressings that have been, and are now, recommended, but simply give those which I prefer, and also speak of some in common use to condemn them.

The so-called antiseptic practice embodies the great principles of cleanliness and carefulness in surgery, and is now so well established among the best surgeons, that it requires no argument in its favor, as compared with the methods of a few years ago.

Ligatures and sutures of the following material: Silkworm gut, catgut, horse-hair, and silver wire, meet every requirement in ligating vessels and closing wounds. I prefer the silkworm gut, for all cases where considerable strength is required, for ligating arteries, and for deep sutures. Horse-hair answers as well for superficial sutures, and is very easy to adjust, and can be obtained without difficulty; it can be left in place for an indefinite period without producing the least irritation.

I have had trouble in getting catgut that was of sufficient strength to tie important vessels, so of late have used the silkworm gut, and it has proved perfectly satisfactory. The ligatures are all preserved in oil of juniper; and are preferred to those prepared in glycerin and carbolic acid, as when ligating an artery those in oil of juniper will not slip through the hand in tying, and the knot can be made more secure, and is less liable to slip.

Sponges should be dipped in 1 to 3000 sublimate solution, and squeezed as dry as possible; and under no circumstances should they be used for a second operation.

In a large majority of operations it is much better not to touch a sponge or anything to the cut surfaces, as the parts can be cleansed more satisfactorily by irrigating than with the sponge. Now it may be said that this is not practical in every day work outside of the hospital and office; but there are very few places where we are to operate, in which this plan cannot be carried out satisfactorily. It is my custom to have in the case with other dressings, which I have for immediate use, a piece of one-quarter inch rubber hose, twelve feet long; this can be coiled up and occupies but little space, and with an ordinary wooden pail, which can be obtained at almost any house, if cleaned with scalding water and bichloride,

is fit for use; by placing one end of the tubing in the bottom of the pail, and tying the tube to the bale; then hang the pail to a hook or nail, or set it on a shelf, above the operating table or couch, and the tubing makes a syphon, which can be used to keep a hot bichloride solution constantly running over the parts operated upon, and a tub or pail on the floor to catch the water; comprises the apparatus required for irrigation in any operation.

When operating for railway injuries, I have found it convenient to use one of the new large wooden pails which are used for water in cabooses; and draw water for the sublimate solution from the boiler of a locomotive that is fired up, so we can be quite certain it contains no septic germs.

For convenience in preparing the bichloride solution, the antiseptic tablets, manufactured by Wyeth, answer the purpose very well, and a given number of parts to the thousand of water can always be made at a moment's notice.

To produce anæsthesia, I use only Squibbs' ether, in one-quarter pound cans, and open a new can for every case. Whiskey is given previous to etherization, and the ether administered by pouring it upon two or three folded towels, which are held in place across the nose and mouth, and, in my opinion, are preferable to any inhaler, as this method is clean and effectual, and in my hands has never failed to produce complete anæsthesia in as short a time as is desirable, and without difficulty. I believe that the principal difficulty in producing anæsthesia with ether is on account of the quality used, and trusting to that which has been uncorked for some time and exposed to the air. Before adopting the plan of purchasing ether in small cans and opening a new one for every case, I noticed that when using the last half of a pound can, which had been opened for some few days, I had trouble in getting the patients under control, but when a new can was opened it took but a few moments.

Before beginning any operation the part should be shaved and thoroughly cleansed with bichloride solution; the hands of the operator and assistants should be washed with hot water and soap, and then immersed in the mercury solution. The instruments should always be immersed in boiling water, and then placed in a tray containing a solution of carbolic acid and oil eucalyptus; and if the operation is one which requires the use of several instruments, or the same one several times, it is well to have a carbolic solution in a separate dish to rinse them in before returning them to the tray.

"Good drainage to a wound is as potent to its cleanliness as is the good drainage of a dwelling to the healthfulness of its occupants" (Bryant). Various devices for draining wounds are in use, such as soft rubber tubing, of several sizes, with apertures through its walls; Neuber's bone drains, or what is better in a majority of cases, several horse-hairs, a few strands of silkworm-gut, or cat-gut, which can be placed beneath the flaps, at the most dependent portion of the wound, or where accumulations of fluid are most likely to occur; the strands can be removed one by one without producing pain or irritation; but, of course, where the amount of fluid is necessarily large, the bone drains or rubber tubing should be used; however, in a large majority of wounds and amputations the drainage apparatus is not necessary. If proper antiseptic precautions are taken, and the wound completely closed, it will unite without suppuration, when if there was a drainage-tube placed in the same wound, its presence would act as a foreign body and cause suppuration. So I say that in a vast majority of clean operations, it is not necessary to make provision for drainage, as there will be nothing to drain. If an amputation is made properly there is no need for drainage-tubes, if the flaps are made to come perfectly together without stretching, and the edges of the skin made to meet throughout the whole line of incision, and covered with plenty of iodoform and absorbent lint, there will be no discharge whatever, and if there is not more than one or two degrees rise in the temperature, which should be taken every day, with absence of pain, redness, and swelling, we may be certain there is no accumulation of fluid, or pus, that should be drained off. However, if any of these symptoms should arise, indicating the formation of pus, it is an easy matter to remove the dressings and determine the seat of the fluid, and remove a suture, and allow it to escape. If this rule is adopted much more satisfactory results will be obtained without the use of the drainage-tubes than with them; though there are occasionally cases where it is quite certain that fluids must necessarily accumulate unless provision is made for drainage.

Oil silk and rubber tissue are used by many to seal wounds and make the dressings air-tight. It is the opinion of the writer that wounds dressed in this manner are more liable to suppurate, as moisture in a part aids in bringing about just what we should try to overcome, the air-tight dressings prevent the exhalations and perspiration from escaping, which has a tendency to soften the wounded part, and lessen its vitality, and aid in producing a slough, which would not likely occur if the dressings were light and porous.

It is the practice of many surgeons to apply absorbent cotton directly to crushed and cut surfaces. Why this is done I cannot conceive, for all who have undertaken to remove such dressings after they have been applied from a few hours to a few days well know what a task they have before them, as it is nearly impossible to remove all the cotton without considerable injury to the already wounded tissues, and if it is allowed to remain, will act as a foreign body and produce suppuration, which would not occur if at first properly dressed. I have cases coming to me nearly every week which have had wounds dressed by applying absorbent cotton, and sometimes ordinary cotton batting pressed directly into a gaping wound. Pads, or bags of peat, sawdust, jute, wood-wool, etc., are worse than useless. I have had several cases sent to me for after-treatment with the wounds filled with fine sawdust. One was a case where two fingers had been amputated the night before, the third and fourth fingers near the hand; the flaps were not half closed, and the

cavities between the flaps filled with sawdust; the hand was in a bag containing about a quart of the stuff. The flaps were not sufficient to cover the bones, so they were reamputated twenty hours after the first operation, irrigated with hot bichloride solution, and dressed with absorbent lint and iodoform. The stumps healed without the slightest discharge, and required dressing but once after the amputations.

The immediate dressing of wounds is very important, as the whole future progress of the case depends upon the first dressing.

So-called temporary dressings of wounds are worse than useless; it would be much better if no attempt at dressing a wound were made until proper cleansing, closing of wound, and permanent dressings could be applied.

Every physician who treats injured persons can easily have a case, which should always contain necessary materials for dressing all cases of injury to the soft parts at a moment's notice, and I consider this of the greatest importance; as I said before, the first dressing should be made as soon as possible after the receipt of the injury, and if all the requirements of clean and proper dressings are not fulfilled at first, they will not be of much avail afterwards; so it is always best to be prompt and thorough, paying strict attention to every detail.

Iodoform, in my opinion, has served its best purpose when suppuration in the wound has commenced, and should then be discontinued, and the parts cleansed with hot bichloride solution, the frequency of such cleansing depending upon the amount of discharge from the wound, and other dressings applied. The dressing which I prefer, after suppuration is established, is composed of linseed oil, 1 pt., crystals carbolic acid, 1 dr., oil eucalyptus, 2 dr. Mix and apply several layers of absorbent lint, saturated with the oil, at each dressing; this dressing is also used on all suppurating and granulating wounds and burns, taking care not to remove the dressings on large granulating surfaces too often, as, if removed too frequently, the granulations will be wounded and bleed when the lint is pulled off; on the other hand, if left two days or more, a sufficient quantity of creamy pus will form under the dressings and allow it to come off easily, and without irritating the delicate new formation of integument. This dressing has been applied to granulating surfaces where skin grafts were used with good results.

Some authors advise being cautious about the use of iodoform on extensive wounds, especially of the scalp, on account of its effect upon the nervous system. I have never seen any bad results from the free use of this drug, and have used it in very large quantities; but, of course, always close the wound as perfectly as possible, then literally cover the whole tract of the injury with it, and then with lint, which is left in place until the wound is healed.

In January last I was called to dress a scalp wound for a man forty-five years of age; it was through the scalp, partly lacerated and partly incised, and produced by falling on an old shovel. The wound extended from a point midway between the left eye and ear, diagonally over the top of the head, nearly to the occipital protuberance, and measured thirteen inches in length. The hemorrhage was profuse. Three arteries required ligating; the hair was cut away from the scalp along the track of the wound, and the parts thoroughly cleansed with hot water, containing bichloride mercury, 1 to 3000. The arteries were tied with silkworm gut, and the wound completely closed by sutures of the same, set every three-fourths of an inch; then the whole line of wound was thickly covered with iodoform, and four layers of absorbent lint over this, held in place by roller bandage and adhesive strips. The patient was kept quiet in bed for a few days, and suffered no pain or inconvenience whatever; the dressings were removed on the tenth day, and the wound was found healed completely without any discharge whatever. The sutures were left in place for six weeks, and did not produce the slightest irritation; on removing them, it was found that the portion passing through the scalp had nearly all been absorbed. (The sutures were left with a view to ascertaining the length of time it would take for them to become absorbed.) I have used silkworm gut for ligatures, and cut the ends short, in four cases of amputation of the forearm, and all have healed without suppuration, so I was unable to ascertain whether the ligatures were absorbed, or merely became encysted, though I am inclined to believe, from the result of the experiment with the sutures, that they are absorbed the same as the catgut, but not as rapidly. I think when the silkworm gut is used to ligate arteries, that it would likely be absorbed sooner than when used as a suture in the skin.

Adhesive strips should never be applied directly to the flaps after amputations, as they always do more harm than good by increasing the liability to sloughing, by obstructing the already feeble circulation. Neither should they be placed across a wound without first applying absorbent lint over the wound, which should extend a considerable distance beyond the injury.

Dressings can be made to stay in place smoothly for a long time by putting on narrow strips of adhesive plaster, which should cover the edges of the outer layer of roller bandage, having previously applied a few strips lengthwise the limb, or across the turns of the bandage.

This kind of plaster can be torn in strips of the required width as fast as they can be applied, and is much more convenient than plaster that requires to be cut in strips.

Dressings applied to stumps after amputations should be put on smoothly and uniformly, so as not to press the flaps against the sawed end of the bone, and when the amputation is through the leg the flaps can be well supported by the apparatus illustrated and described in my paper on Railway Injuries.

It may be of interest to some present to see the contents of the dressing-case which I at all times keep stocked for immediate use, besides a much larger one kept at the railroad yard office in case additional supplies are required.

This case contains: Absorbent lint; absorbent cotton; rubber adhesive plaster; silkworm gut; catgut;

horsehair; antiseptic tablets; whiskey; ether; crystals carbolic acid, and oil eucalyptus; Esmarch's bandage; cotton roller bandage; rubber tubing for syphon; sponges; drainage tubes.

THE CURSE OF SCHOOLS.

By WALTER D. BIDWELL, A.M., M.D. (HARVARD),
LEAVENWORTH, KANSAS.

UNDER this title I wish to present the views of some of the wisest physicians of this century, as well as my own, in relation to schools of medicine.

A part of this article appeared under a different caption in a western journal two and a half years ago.

Its appearance at this time is provoked by an editorial in the *Medical Register* of March 9, regarding a communication from Dr. Mickle, of Baltimore.

As will be seen further on, I not only endorse what is stated editorially, viz., that we are "warranted," but I claim that we are *morally bound* to use all the weapons we may be able to control for the accomplishment of our purpose, the healing of the sick. And if Dr. Mickle and his numerous fellowship of hobby riding, narrow-minded "paths" of every description would read up the matter a little so that they really knew what they claim to believe, common sense would lead them to disclaim the monopoly of any one method of curing disease.

There are many men whose ideas are so limited, whose minds are so narrow, that one wishes they could be transported to mid-ocean to extend and broaden their views.

This is a wide world, and the true man is interested in affairs outside his petty burg, and is able to grasp the fact that there are other and larger towns than his own. Of these he desires to know something, and when he finds more enlightened modes of living, adopts them in his own home.

This is what is needed in the medical world, that its occupants shall step outside the ruts wherein they were educated and not be content to live as their fathers did.

In unity there is strength, and whilst we must have divisions and sections owing to our locations and personal preferences in investigating special branches, there is no need of the divisions into so-called homœopaths, allopaths, etc.

I feel sure that if every eclectic, every homœopath, every allopath knew what these designations meant, if he had been taught the reasons for these names with his anatomy, he would discard them instantly, and in the hope that some may learn what they mean this article has been written.

To make the matter as clear as possible, we shall consider:

1. What is medicine?
2. What is a physician?
3. What are the different schools of medicine?
4. Wherein do they differ from true medicine?
5. What have they contributed to the science of medicine?
6. What line of conduct should we pursue in our intercourse with those who practise medicine according to these beliefs?

(1) The first question is answered comprehensively by the definition: "Medicine is a science which aims at the preservation of health, the cure of diseases, and the physical perfection of man." In this discussion, that portion of medicine embraced by the clause "the cure of diseases," or, to speak more exactly, the methods of administering drugs in their cure, will occupy our attention principally.

(2) According to the derivation of the word, a physician is a follower of nature; but, in the common acceptation of the term, he is a practitioner of medicine, one who devotes his life to the art of healing; and, if he be a true, broad-minded, philanthropic physician, one who uses every available agent to cure his patient.

(3) What are the different schools of medicine? Unfortunately, their name is legion. Suffice it to mention a few:

Hydropathy, which treats all diseases by water, internally or externally, hot or cold, or all combined.

Antipathy, which professes to cure diseases by using drugs that are *opposites*, as if a drug and a disease were opposites, like heat and cold. Its watchword is *contraria contrariis curantur*.

Alleopathy, or *allopathy*, which professes to remove all ills that flesh is heir to, by drugs producing effects *different* from the symptoms manifest in the patient.

Homœopathy, which claims that every medicine in the universe, when administered internally in a healthy state of the system, is capable of producing a certain chain of effects, and that when symptoms similar to these effects appear in disease, these substances will remove them. This is the essential doctrine of homœopathy; but, as this is by far the most important school of to-day, I will speak more at length of it after mentioning one or two others; and first the school of

Eclecticism, whose members are supposed to select from all other schools those ideas which please them. It is based upon Thompsonianism or botanic medicine and was changed to admit the use of minerals. This name is less objectionable than others, but even this implies restrictions. It implies that there are schools of medicine and that eclectics select certain methods according to a fixed rule. There is, however, no such rule, and there can be no school where there is no similarity, except in that each one follows his individual bent.

Isopathic treatment consists in using the identical cause of the disease to cure it, and, apart from the doubtful results which would be likely to follow in many instances, it is manifestly impracticable as a system of medicine.

It is useless to mention *rationalism*, *animism*, *iatrochymia*, etc., as they are too abstruse or too absurd for us to endeavor to comprehend them.

If any one wished to give a name to the regular practice of medicine as it is to day, it might be called *empiri-methodism*, whose doctrine is that a treatment which has procured the cure of any disease whatever, will cure, also, all diseases identical, or rather homogeneous, with the first.

Turning again to homœopathy, as the only school deserving of consideration in connection with the

regular practice of medicine, we find its followers holding strongly to other beliefs besides those of similars; for example, that the power or virtue of the drug used increases in an inverse ratio with the size of the dose. This is an article of faith which many follow religiously in their practice. They also claim that the action of a drug can never be learned by watching its effect on a sick person, but only by studying the effect it produces on the healthy organism, or, as they call it, by proving. Of necessity, then, the homœopath treats symptoms and diseases.

(4) For a proper conception of the value of any method of treatment we should bear in mind that the physician called to a patient is requested to cure his disease; but he has not the simple task which a laborer summoned to remove a rock has, he does not remove the disease by simply using his muscles or giving some drug which banishes it, leaving the body as it was before, as water poured on a piece of soiled glass removes the dirt; but having correctly diagnosed the case he sees that some of nature's laws have been violated, and he enjoins such methods of eating, drinking, sleeping and exercising, as are in conformity with nature's laws, and, perhaps, supplements this with the administration of some drug. This drug may be a specific, *i. e.*, like quinine or mercury, it may be a direct antagonist to some poison, or it may restore the free action of the skin, as in the case of aconite given for febricula; but in any case it is secondary and an adjuvant to the vis medicatrix naturæ. Nature tends to preserve a *mens sana in corpore sano*, to throw off disease herself, and all that is asked of the physician is that he remove such obstacles as stand in her way. The more this idea is emphasized the less danger there is of overdosing or of errors in medication generally.

Now, wherein do these systems differ from the regular practice? I answer, regular medicine comprehends that which is beneficial in the treatment of disease in *all* of them, and includes much, much more that falls outside the limits of their narrow-minded theories. Hydropathic treatment at certain times and in given cases contributes to a cure; to that extent it is a part of regular medicine. But hydropathic treatment will not cure *all* diseases, and other methods of treatment will cure *some*. Therefore, hydropathy is not a complete system of medicine by itself. Likewise, antipathy, allopathy, homœopathy, all have certain applications in medicine, certain drugs and diseases will prove each doctrine, certain others will as surely disprove each. But the spirit of man is inclined to generalize even the most exceptionable facts, hence so many systems. Both *contraria contrariis curantur* and *similia similibus curantur*, and all other preconceived theories must be erased from therapeutics, at least as general axioms, if we wish to rest this science on a solid basis, whose stability no one can shake. For, as in all other sciences advances are to be made only by seeking for truth with unbiased judgment, so in medicine truth can never be reached if the investigator starts with preconceived theories and makes his discoveries fit them. No theory yet discovered explains *how* drugs cure diseases, neither do we know *how* soul and body are united, and it is not necessary that we should know. But all we can know certainly, all that assiduous observation can teach us is, that the cure of such a disease succeeds more or less constantly the administration of such a remedy. When our treatment of disease is based upon this foundation, then, and only then, shall we have a reliable system of therapeutics, and be fitted to practice the art of healing; provided, of course, we have sufficient knowledge of anatomy, physiology, pathology and chemistry to determine homogeneous cases of disease.

At a meeting of homœopaths at Kansas City three years ago, one of the essayists made a most uncalled-for and scurrilous attack upon non-homœopathic practitioners, and his remarks were published in the daily papers. Those who read the article will doubtless agree with me when I say that homœopaths in arguing against regulars have adopted a very specious method; and it is necessary, in refuting their arguments, to bear in mind the following facts, viz.: a regular physician is not an allopath, nor an old school man. When Hahnemann and his followers took the name homœopaths, they assumed that all non-homœopathists were as narrow minded as themselves in another direction, and classed them as allopaths. But for this mistake of claiming to found a new school, Hahnemann would have been honored to-day by *all* physicians, for instituting much needed reforms in one department of medicine, for this is the proper place aud rank of homœopathy, and all that it amounts to. The reforms I refer to are: First, a reduction in the size of doses, for, undoubtedly, too large doses were common at the beginning of this century; but this reduction must not be carried too far. There is a limit to the subdivisions of a drug, each one of which shall be as efficacious as the preceding, to say nothing of its being more powerful, as Hahnemann claims.

The only valid argument in favor of the use of minute doses is based upon a comparison of the results obtained by using them and larger doses in precisely similar cases. Such a comparison may give results that will weigh strongly in favor of minute doses, and, when this is proven to me, I am ready to accept them as more efficacious than those I now employ.

Who does not object to excess of dosage? It has been and is practised by many, but no one is compelled to follow the example of such, and the best practitioners are not guilty of such mistakes, any more than do the best homœopaths believe in the indefinite divisibility of matter. The minute doses now common with many regulars would satisfy any *reasonable* man.

Again, polypharmacy was carried to the extent of mixing fifty or sixty drugs in one prescription, and to Hahnemann is largely due the credit of the growing tendency towards the use of single remedies, and at the same time to diminish the amount of dosing; though this still varies greatly with different physicians. But this could have been accomplished as surely without attempting to form a new school, or if it could not at that time, now that the reform has been introduced, such school is no longer needed,

but its very existence prevents other equally desirable reforms.

However, the fact remains that Hahnemann did found such a school, and it has existed ever since, and the easiest solution of the problem now is to accept what wise suggestions he made, to ignore those absurd ideas which led Dr. Holmes to make his severe criticism on homœopathic physicians, and to drop the distinctive name.

Dr. Wesselhœft says, "No school can, in justice, call itself 'regular' while it excludes from among its methods and principles this one practical element, viz.: *similia similibus curantur.*" Well, I believe he is right. This fact is well established regarding certain drugs, and, so far as I know, no one wants to deny it. This peculiar action regarding such a drug as ipecacuanha, which had been used by regulars centuries before Hahnemann was born, is an undoubted fact, and no one but the homœopathists have suggested its exclusion as a drug which the regular physician cannot conscientiously use. But the regular physician does claim that there are drugs concerning which this has not been proven, drugs that benefit the sick, and, therefore, are medicines which no man who practises homœopathy conscientiously can use, and he claims that the homœopathist is doing an injury to his patient in refusing to use those agencies which would hasten his recovery. True, medicine is too broad to be assailed, and asks no one to abate one whit of his powers for relieving suffering, asking only that things be called by their right names, that distinctive appellations which work no benefit, but merely interfere with the onward march of true knowledge, shall be done away with, and that the physician decline no aid, which shall benefit his patient, merely to live according to an ancient dogma.

The essential doctrines of homœopathy, the formula of similars, the proving of drugs, and the use of single simple remedies in small doses, are confessedly insufficient, and no homœopath will rely upon his similars and small doses in treating a person who has been poisoned by morphine or strychnine. Who ever heard of one giving morphine to a man who had swallowed an overdose of the drug?

Statistics are sometimes quoted to show how much lower death-rates are found in homœopathic hospitals than in the non-homœopathic. In these are two principal sources of error. First, there is an almost universal belief in this country, and, without doubt, to a certain extent in foreign countries, that homœopathy is good for slight ailments, but that serious sickness requires the presence of regular physicians. Such being the case, the number of deaths per one thousand will, of course, be greater in the wards of non-homœopathic hospitals, where the majority of severe cases of disease is taken. A second source of error was pointed out to me by a druggist, who said that in one year he sold a moderate sized homœopathic hospital over $400 worth of morphine. How many similar doses do you imagine were in this wholesale quantity? The dosing that took place there must have resembled that cotemporaneous with Hahnemann. In fact, a hospital was founded in Pennsylvania to test homœopathy; after some time it was ascertained that some of the physicians were transgressing the essential doctrines, and they were ordered to observe them strictly. What followed? The whole staff resigned, giving as their reason that in justice to their patients they must use agencies which were not in accord with those doctrines. There is the whole matter in a nutshell. Homœopathy is not broad enough, but its followers cling to their tattered standards, believing that they must enlist under the banner of some school and follow some pathy, whereas their energies could be much more profitably employed in healing the sick by the use of any and all agencies known, than in trying to conform to a single theory, or trying to make the people believe that they do.

And now, finally, what should be our action towards those who claim to practise medicine under such restrictions and limitations as any one of these 'pathies implies?

Our code says: "No one can be considered a regular practitioner, or a fit associate in consultation, whose practice is based upon an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry."

It does not say "any homœopathist," and if a man calls himself a homœopath merely because he uses small doses of so-called homœopathic drugs which he has found to produce the best results in healing; if he makes use of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry, in forming a diagnosis and determining proper treatment, he is in reality a regular, and entitled to be met in consultation, though mistaken, and, perhaps, innocently so, in styling himself a homœopathic physician.

Since the foregoing was written, I have seen a similar statement of the celebrated Dr. James Jackson, which is as follows: "Some of the homœopaths undoubtedly do not confine themselves to the practice of Hahnemann; they do not profess to do so. They say that disease can be relieved and removed in different modes, and that they choose in each case that which they think best adapted to the case. To you and to me there seems to be an inconsistency in this. If the principles of homœopathy are true and well founded, all other principles as to therapeutics must be false, and evil must follow if these be regarded in practice. But if another man fails to see this inconsistency, or asserts that he does, I do not see that we should refuse to deal with him more than with any other man who differs with us on important points."

Homœopaths say that their school is nothing if not practical; they are governed by that alone which they can know or discover positively; that in daily practice they think it unpractical to make the positively observed and easily observable facts subordinate to theoretical or even hypothetical data. Yet because some drugs are known to cure diseases manifesting symptoms similar to those produced by that drug in the healthy organism, they reason that this s true of all drugs. This appears to me to be the

height of unreason, and exactly what they condemn as unpractical. As well claim that because all the men you meet in one hour's walk are white, therefore all you meet in the succeeding ten minutes will be white. The true homœopath swallows some very specious reasoning, and must have faith. It is admitted that provings are of most value when verified chemically, and that other drugs not proved, but chemically shown to be satisfactory, are also used. This is rational, but the absurd part of homœopathy comes to the front in the exclusion of the latter from the materia medica pura, which is the simon pure homœopathist's Bible.

If, however, a man is living up to the Hahnemannian doctrines and neglecting the aids mentioned above, he is certainly not sufficiently educated to be met in consultation, and if you inquire into the matter you will find the majority of so-called homœopaths join you in calling him a fool. The same reasoning applies to all other 'pathies, and if we were, as homœopaths style us, allopaths, we should be equally excluded, by the letter and spirit of the code, as the most intense high dilutionists on record.

The code wisely mentions no "paths," but some years ago the Massachusetts Medical Society went beyond the code and excluded homœopaths from the Society. This was a great mistake, as it made the homœopathic physician appear in the rôle of a martyr, and public sympathy went with him; and this action of the Society, intended to stamp out homœopathy, is regarded by many physicians as one of the main causes of its present strength in that State.

The remedy for this curse of division is the promotion of knowledge. Let every medical school in the country devote one or two hours a year, at least, to giving the students a clear understanding of what these old divisions imply, encouraging them to be honest physicians, and to labor for the good of their fellow-men. A physician should be broad-minded and above petty strifes. His profession is of itself most honorable, and there can be no nobler title than that of true physician. The dispersion of the clouds of ignorance will assuredly bring about the result desired.

My reason for the ground I take can be summed up in a few words. I object, as strongly as any member of the profession, to the existence of schools of medicine, such as homœopathic, allopathic, eclectic, etc.; but they cannot be gotten rid of by excluding practitioners from societies and associations; for the method has been tried, and only added fuel to the fire it was intended to quench. They form societies and associations of their own, and gain popular sympathy by posing as martyrs.

We must meet them as gentlemen, and by argument and reasoning show on what false ground they stand. We must convince them by sound reasoning that medicine is a much broader field than homœopathy, for it covers *every* pathy; and, avoiding the vituperative style of many of Hahnemann's followers, we should prove the narrow-mindedness of his system.

It is most true, as a translator of the works of Hahnemann remarks, that "the time has gone by when the pleasantries relative to the infinitesimal doses can be regarded as good arguments against homœopathy," and no one clothed with the medical priesthood and comprehending the dignity and importance of his ministry can remain indifferent. We must give the matter a searching examination, and then take part for or against it.

There are some who can find no good thing in Christian scientists or metaphysicians. Now, I must confess that the mass of their so-called science would be more appropriately named after the arch fiend, and I know that they do much harm in the world by their extravagant and nonsensical pretentions. A better description of this so-called science than that of the Rev. Mr. Trusdell, of Chicago, can hardly be given: "A strange hodge-podge or conglomeration of Bible, Koran, Buddha, Shakespeare, the Book of Mormon, Socrates, Carlyle, Browning, Cora Hatch and Colonel Ingersoll; a mixture of orthodox Christianity, heathen mythology, oriental philosophy, and Poor Richard. It is simply a string of proverbs, maxims, moral precepts, recipes, and scientific allusions, with quotations from proverbial philosophy, calculated to bewilder and mystify the ignorant and the credulous, while it can hardly fail to disgust the candid and practical mind." But the power used—viz., belief in some persons' ability to effect a cure, is sufficient of itself to heal many diseases, and is and always has been the most potent agency in the true physician's armamentarium. These facts must be borne in mind and allowance made for the grain of truth, while we do away with the bushels of falsehood which these false saints try to conceal under their high and sacred names.

Just here I would like to read a letter from Dr. V. Y. Bowditch, of Boston, in reply to the question, "What stand does the Massachusetts Society take as regards members who consult with irregulars?" and "Do you think there is any chance of the distinction between the different schools being done away with?" He says:

"I do not doubt some question would arise in the councils of the Massachusetts Medical Society as to the admission of one who was honest enough to confess at the outset that he did consult with homœopaths when occasion offered, but I think the feeling among the *younger* members of the profession certainly, and also among many of the older ones, would be, that such questions should be a thing of the past, and that the chief question should be, "Is this an educated physician, and is he an honest man?" I know of no case of expulsion for consulting with homœopaths or eclectics, and I should doubt very strongly if it would now take place, although the rules of the Society still forbid it. I am sure it is more frequently done than is known, and in my opinion such clauses should not exist in our laws.

"I sincerely hope, and have reason to believe, that the day will come when the distinctions between the 'schools' will be a thing of the past among properly educated physicians. As long as hope is in us human beings, however, there will always be 'isms' and 'pathies' of some sort or other, and my belief is that

we can often find a grain of truth in the bushels of chaff which are brought to our notice, and that persecution of the originators of such ideas is folly. It only makes martyrs of them in the eyes of the public generally."

During the past year the Massachusetts Medical Society has made other changes in its regulations tending in the direction prophesied by Dr. Bowditch, but I cannot lay my hands on the paper containing the report of them.

In closing this paper, I will state what has already been done towards securing that harmony in the ranks of physicians, the lack of which has been continually lowering us in the eyes of the public. In 1885, the Boylston Medical Society of Harvard, of which I was at that time a member, invited Dr. Wesselhœft, a prominent homœopathic physician, of Boston, to lecture before it on homœopathy. At his request, a series of questions was proposed by the members, and, after he had answered them, a free discussion of the subject followed with the result of enlightening the members, if it did not convert the lecturer. Again, the following summer, the Hahnemann Society of Boston University invited Dr. V. Y. Bowditch, who had been President of the Boylston Society in 1885, to lecture before it on homœopathy and the regular practice; which he did, and the lecture has been published in an Eastern journal.

I quote from the *Medical Record:* "A good man struggling with adversity is a sight which ought to awaken lively and sympathetic interest. Such a sight is presented by the New York *Medical Times*, which, for some years, has been manfully endeavoring to rid homœopathy of its sectarianism and distinctive name, while still claiming that it represents one of the most important therapeutical principles. In consequence of its course it is receiving severe criticism from many of its quondam brethren, while it gets a very unappreciative hearing from the regular school. For example, one of our contemporaries prints the following, apparently unaware that the *Times* has been saying this same thing for several years:

"*Homœopathists Getting their Eyes Open.*—The following remarkable passage appears in the (homœopathic) New York *Medical Times:* 'Go on in your sectarian course ultra-devotees of Hahnemann, if you will, be loyal to the teachings of your master, but shut your eyes to the fact that science has rendered obsolete many tenets of his system, and removed the last vestige of an excuse for maintaining an organization of physicians under an exclusive title, distinct and separate from the medical profession at large. The ultra school of medicine has fulfilled the complete measure of its usefulness as a separate organization. Loyalty to truth and progress now demands that it shall drop its narrow, sectarian name, and no longer seek to keep its members in leading-strings. In the nature of things, there can be but one system of medicine recognized by science. Either homœopathy must absorb the old school or be absorbed by it.'

"It would be better, we think, to give to such sentiments our hearty endorsement, with success to those who utter them."

Such meetings as those just mentioned, with the full reports of them in our medical journals, and the persevering efforts of such men as the editor of the New York *Medical Times*, will contribute materially to that clear understanding of our relative positions necessary to unite all physicians under one standard. We are public servants, but our service is high and important; and we should jealously guard the reputation to which our profession is entitled.

DIPHTHERIA.

(Read before the Jefferson County Medical Society.)

By G. HERBERT DAVIS, M.D.,
BLACK RIVER, N. C.

IN consideration of the fact that this disease has spread its baneful effects throughout the world, and received the attention of the greatest minds of the profession, without any specific or preventive treatment being found, it seems to me that instead of entering into the various theories in regard to etiology, we should treat of it in its practical aspects.

It is generally conceded that the disease is an associate of filth and bad hygienic surroundings; bnt this is not always the case, as epidemics are well known to occur in families and localities where the best sanitary regulations prevail.

It spreads its baneful influence alike in cities where good systems of sewerage are the rule, and in the country where slops and excreta are thrown upon the ground, or run into the vaults of privies which are not emptied until full.

It destroys alike the rich and poor, but seems more fatal to children than adults, though many of the latter are numbered among its victims.

The appearance of diphtheria in a community today is more dreadful than was smallpox in the days when the older ones among you were beginning the practice of medicine.

And well it *may* be dreaded; for, when epidemic, whole villages and towns are put in mourning for their little ones. I have myself seen five members of one family die within twenty-four hours from this dreaded disease.

It remains a source of the most profound regret to the profession at large that, as yet, no specific cure, or preventive means, has been discovered to render the spread of so fatal a malady an impossibility; and a fame far in excess of that of Jenner, Pasteur, or Koch awaits the first discoverer of a sure preventive or specific cure for diphtheria.

I consider myself exceedingly fortunate, that, in a practice extending over a period of five years, I have been called upon to treat but few cases of diphtheria, the whole number of cases treated being twenty, and the number of deaths two.

I consider the disease to be a constitutional one at first, with local manifestations, and that the re-formation of membrane after its extensive destruction, as practised in the past, goes to prove this fact.

Were this not so, many cases seen early in the disease, when the membrane is confined to one or more small patches upon the tonsils, could be rapidly cured by caustics or cauterization. Whereas, I know, by

my own experience and that of others, that this is not the case. Instead, the patches thus destroyed rapidly recur.

Early in the course of the disease important blood changes take place, such as softening of the spleen, congestion of the liver, and disturbances of the stomach. The symptoms are both constitutional and local, and both may be mild or severe, but there is not always a uniformity of severity between them. When ushered in by a severe chill the disease usually terminates rapidly.

There is often paralysis of the pharyngeal muscles, and difficult deglutition. When the disease descends into the larynx the voice becomes hoarse, and finally is reduced to a whisper. There is at first difficulty of inspiration, then, as it advances, difficulty of ex piration, and, finally, unless we resort to intubation or tracheotomy, the patient dies from asphyxia.

In diphtheria the temperature is not as reliable a guide as the pulse. There are no stages and no critical days as in other diseases. It follows no regular laws. Some cases live but a few hours, others live weeks, and, after apparently recovering, may die from paralysis of the heart.

A rapid pulse does not render the prognosis more grave, unless it is also irregular. Vomiting at the outset is not dangerous, but toward the termination is more serious. Delirium, late in the disease, accompanied by a typhoid condition, or stupor, heralds approaching death.

The prognosis is *always* grave. In epidemics nearly 50 per cent. of the cases are fatal. The cases at the beginning of an epidemic are more serious than towards the last.

As regards treatment, too many methods are in vogue for me to enumerate them. Therefore, I will only outline the treatment used by myself, in recent cases, and which has proved more satisfactory than any previously employed.

If called early in the disease, I give a laxative dose of calomel, cause the patient to be isolated, and allow only necessary attendants in the room. I evaporate turpentine or bromine and generate steam in the room, keeping the patient as quiet as possible.

For local treatment I use insufflations of boracic acid, iodoform or sulphur, and spray the throat with a solution of sulpho-carbolate of soda, allowing the same for a gargle.

I usually allow them to wear a piece of fat pork sprinkled with salt and pepper, around the throat, and make no efforts to remove membrane, unless it is partially detached and hanging in shreds. so as to interfere with respiration.

I have more confidence in constitutional treatment, and aim in that to support the strength, and recuperate the failing powers of the patient, combating the septicæmic condition with tonics and stimulants; such as tincture of iron, from ten to forty drops, suspended in glycerin and water, once in three or four hours; alcohol in some form given in milk and lime water in large doses, sulpho-carbolate or sulphite of sodium as a germicide. Quinine or antipyrin for excessive pyrexia. Digitalis, ammonia, or tincture strophanthus, as a support to a flagging heart, and as much nourishment in the form of milk, beef tea, gruel, etc., as I can induce the patient to take without stomach disturbance.

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL.

Clinic of PROF. J. M. ANDERS.

INDIGESTION.

THE first case that I have to show you to-day, gentlemen, is one of indigestion, in a little boy, F. G., aged six years, who first complained of his present trouble about three weeks ago. This affection is a frequent one in children, and the reason for it is evident, when we remember that the cause is, as a rule, improper feeding. Immediately after eating the patient feels uncomfortable, with a sense of weight and fulness about the gastric region; there may be some nausea, rarely vomiting, and slight diarrhœa, or, at least, an occasional soft stool with small masses of hard, undigested food commingled, often follows. Palpation determines usually a distended stomach, which is tender on pressure. The prognosis is always favorable, the local pathological condition seldom exceeding a slight gastric catarrh, perhaps; although, if left untreated, the patient suffers from an impairment of general health and strength, that may become seriously intractable.

The treatment of indigestion naturally divides itself into two heads, namely, the hygienic and the medicinal. Careful regard must be paid to regularity of eating, kind and quantity of food. Generally speaking, milk, light soups, eggs, bread and jelly, and the like, are well taken and easily digested. When, however, the digestive function is feeble on account of an insufficient supply of the gastric juice, recourse must be had to medicines, the essential remedies being pepsin and dilute hydrochloric acid. Two grains of the former with three minims of the latter, as a dose, taken well diluted, after meals, will ordinarily meet the indications, in a child six years of age.

CHOREA.

This little girl, also aged six, the mother says, complains of a peculiar twitching of the left arm, which is at once noticeable. We recognize this as an undoubted case of chorea, involving principally the muscles of the left shoulder, hence unilateral. We have the history of this malady dating back one year, apparently because of the resisting nature of the affection to drugs, and the fact that implication of one or two groups of muscles seems to be more difficult to cure than do the general choreic movements. The predisposing causes of chorea, age and sex, are admitted to be important in the etiology of this disease; whilst fright is denominated an exciting cause. This affection is, as you may all know, common to the young almost exclusively, especially at the period of approaching puberty. In the aged, the pathological condition is supposed by most authorities to be entirely different from that of childhood; and senile chorea—only thirteen distinct cases of

which have thus far been acknowledged as properly recorded—certainly is much less amenable to treatment. As to sex, it may be remarked that chorea is more frequent in girls, in the ratio of about two to one, compared with boys. Again, specific disease and overwork may play no inconsiderable part in predisposing to choreic attacks. Rhematism often bears a peculiar relation to chorea; and in the case before us there is a family history of rheumatic trouble—in the father we are told. Chorea may be, and rarely is succeeded, even years after the first attack, by rheumatism; hence, we should make it a point invariably to auscult the heart in all of our patients who are afflicted with this nervous derangement. However, in this little girl we can discover no murmur, but, what is rare, a reduplication of the first heart sound.

Before an actual attack of chorea, premonitory symptoms of restlessness and peevishness on the one hand, or excitation and abnormal buoyancy on the other hand, manifest themselves. Then, the involuntary twitching of one group of the skeletal muscles, steadily advancing until the whole system of voluntary muscles are involved. To develop an attack fully, a week or ten days after the signs before mentioned first appear is required. The twitchings may become so violent as to throw the patient from a chair, or out of bed. We observe now that the left leg twitches slightly in our little patient, thus justifying the appellation of hemi-chorea to this case.

The pathology of this affection has been ably studied by Dickinson, who has shown that hyperæmia of the brain and spinal cord exist, and, in severe cases, extrusion of the contents of the blood-vessels into the adjacent tissues is evident. In treating chorea, no great beneficial result is to be expected in the first week of medication, as, by using the best remedy we have, namely, arsenic, the symptoms may be aggravated. This drug is administered best in the form of Fowler's solution, giving gtt. iij after each meal, and increasing the dose by a drop every two days to the point of toxicity, watching the effects carefully. When given internally without benefit, arsenic may be tried hypodermatically, injecting three minims of the solution once daily, and augmenting the dose one minim every second day. The next remedy in point of service is cimicifuga, while Ross claims good results from the use of the sulphate of zinc. The fluid extract of cimicifuga in ten-minim doses to begin with, increased gradually to fʒss, may be given; or, bromides in combination with a simple bitter tonic, as gentian and iron, may prove to be efficient remedies. The vegetable salts of iron are to be preferred for children, as they are more easily assimilated.

MITRAL REGURGITATION.

Wm. B., aged ten, suffers from a cardiac affection of one year's standing. Family history good. Oppression, with slight pain about the region of the heart and in a few of the joints are complained of. It is worthy of attention and emphasis to note here that, no matter how significant or severe the general heart symptoms may seem, no diagnosis can be truly established except by the aid of physical exploration. We know this case to be one of mitral regurgitation; but we shall now reëxamine the patient before you, detailing the physical signs which form the basis of our diagnosis.

On inspection we observe that the area of impulse is almost twice as large as it should be, and that a heaving of the left chest takes place with every beat of the heart. Palpation confirms this view, for by placing our hand over the disturbed area an exaggerated impulse is appreciated. On percussing the chest, the cardiac dulness is found to extend fully half an inch to the right of the normal external line, nearly as high as the second costal cartilage in the left infra-clavicular space, and about half an inch to the left of the anterior axillary line of the same side. Hence, we have here undoubtedly a case of enlargement of the heart. Is it a simple hypertrophy merely, or is there valvular disease as well? Now, to ascertain this, by auscultation we hear a distinct murmur at the base of the heart, which increases in intensity as we approach the apex, which is further transmitted to the infra-axillary space and as far as the angle of the left scapula.

Here, then, is a defect of the mitral valves, which, closing improperly, permit a reflow of blood into the left auricle with every cardiac contraction; while the hypertrophy is compensatory, on account of the heart's effort to overcome the loss of blood to the systemic circulation which entails upon the regurgitation. But, by and by, this cardiac hypertrophy, this overstimulated heart muscle, loses its tone, degenerative changes set in, and a tendency to gradual dilatation follows; the heart's action, as in the case before us, becoming somewhat feeble and irregular. Mitral insufficiency or regurgitation must not be confounded with mitral stenosis. It may be well to note the following points of difference: First, as to time, the murmur in stenosis of the mitral valves usually precedes and runs up to the first sound; while in regurgitation it is synchronous with and fades away from that sound. Secondly, in mitral stenosis the area of greatest intensity of the murmur is localized within a few inches of the apex beat, and is never transmitted. Thirdly, the character of the stenotic murmur is usually described as being "long and churning," and accompanied by a perceptible thrill; that of the regurgitant murmur, as "blowing."

Mitral regurgitation in children has its origin commonly in a previous endocarditis, due to rheumatic diathesis or to a transient attack of rheumatism that the parents may have overlooked; yet by some it is claimed to originate spontaneously and insidiously. The affection may also follow exposure, or perhaps any one of the exanthematous diseases; but in the majority of instances, although no clear history of rheumatism can be obtained, to it must be attributed these endocardial lesions. They consist in thickened, incrusted valves, agglutinated sometimes to the chordæ tendineæ, and often with deposits of fringe-like vegetations—all due to the precedent inflammatory affection.

The prognosis depends on the most marked feature of the case. Here there is no œdema, but difficulty

in breathing, and the rapid development of the trouble must modify a favorable outlook to a guarded opinion, especially as emaciation has supervened to a marked degree. With care, however, the case may improve as the child grows. In treating this boy, close and rigid attention to proper nutrition and muscular hygiene are essential to invigoration and a possible cure. Light outdoor and gymnastic exercise, the daily bath with dry rubbing, highly nutritious and easily digestible diet are necessary to the end of making blood and muscle. As the indications may suggest, the physician should prescribe tonics, probably the bitter tonics and iron, and when the cardiac contractions are feeble or irregular, the tincture digitalis or strophanthus. Tr. gentianæ comp. fʒss., with ferri et potassa tartrat., gr. ij., will be given in this case, together with ɱ v tr. digitalis.

AT the Philadelphia County Medical Society, September 11, Prof. Keen described an operation which he had performed upon a youth whose ears were too prominent to suit his tastes. A spindle-shaped segment of skin was removed from the back of the concha, and a wedge-shaped piece of the cartilage; care being taken not to cut through the integument in front, which would cause a scar, or to remove any of the anterior surface of the cartilage, which would cause puckering of the skin in front. The ear was then bent back until the surfaces of the cut in the cartilage were brought together, and the skin was united by sutures. Photographs were shown representing the patient previous to and after the operation, and the improvement was manifest.

Prof. Keen also exhibited a case of Dupuytren's finger contraction, cured by excision of the contracting band. The patient, a physician, was present, and showed that he had very good use of the member.

TREATMENT OF LEPROSY.—In the treatment of this disease J. L. Donnet states that the hygienic, the dietetic, and the palliative had more influence than the therapeutic. Where the cleansing of the skin by baths could be effected; where soothing or stimulating applications were made to ulcerated surfaces and to the skin, to allay the distressing symptom of prurigo; where good and abundant food was given, fresh air obtained, and exercise without fatigue taken, with attention to full ventilation of inhabited rooms; where measures were adopted to afford recreation and gentle excitement, and thus divert the mind from the disease itself, a marked difference and a decided improvement were the consequence. Under these influences the disease made little advance. But it is one that follows a determined course, rapid in some, more dilatory and seemingly stationary in others, but never retrogressing, always advancing.

Where drugs were administered internally, he remarked that only those possessed of dietetic properties—as for example, cod-liver oil—were of any value. Mercury, arsenic, iodide of potassium, assacú (obtained by incisions into the bark of the *hura brasiliensis*), ammonia, and other preparations, each acted on the system, *modo suo*, but not in the measure or way hoped or.—*British Medical Journal.*

APOSTOLI'S METHOD.—Dr. A. Lapthorn Smith, of Bishop's College, Montreal, gives, in an interesting and able article, the results of one year's experience with Apostoli's method. He urges the necessity for irrigation of the vaginal canal with a one to one thousand bichloride solution before and after each application, which should be made at least every second day. His experience has convinced him that while electrolysis should not be too highly regarded as a curative means in the gynecological field, it certainly demands earnest and judicious study, and is of undoubted value as a therapeutic agent. Especially is this true as regards fibroid growths of the uterus, which he believes are "primarily due to defective vitality of the uterus accompanied by slowing of the circulation."

The continuous current, he claims, by hastening the circulation, increases the nutrition of the part; the lymphatics take on a new impetus, facilitating the interchange of tissue and absorbing the exuded lymph and products of decomposition, the result of the electrolysis. The relief of ovarian neuralgia by galvanism is also due to this increased nutrition, together with the removal of all retracting plastic effusion. As a means of arresting hemorrhage in fibroids and endometritis, it is universally affirmed that Apostoli's treatment has never failed.

—*Amer. Jour. of Obstetrics*, August.

SUCCESS OF M. PASTEUR'S SYSTEM.—At the Academy of Sciences M. Pasteur recently presented a note of the results observed in the Pasteur Institute from May 1, 1888, to May 1, 1889 (*La France Medicale*, No. 73). During this period 1,673 persons bitten by rabid or presumably (*tres suspects de rage*) rabid dogs had been treated—1,487 French and 186 foreigners. Of this number—viz., 1,673—118 had been bitten in the head or face. Six persons (four bitten on the head and two on the limbs) had been attacked with rabies during treatment; four others were attacked within a fortnight after the close of the treatment. Three persons bitten on the head died after the treatment had been completely finished, and these, therefore, represent the total cases of failure—viz., in the ratio 1 in 557, Or if, 'which would be illogical," adds M. Pasteur, to these three cases were to be added the 10 above mentioned, there would still be a mortality of only 1 in 128.—*Scientific American.*

DR. GEO. C. IRWIN, of Sabetha, Kansas, reports a case of uncomplicated pertussis, with severe laryngeal spasms of hourly occurrence, in an infant aged three months, for which, after using atropia, antipyrin, quinine, and other remedies so often recommended for this disease, he gave phenacetin in one-half grain doses in ten drops of pure glycerin, which is a moderately good solvent, and was surprised to find that it immediately gave relief, so that the first night after using it every four hours the child obtained six and one-half hours' good rest, and there has been a steady and gradual improvement since.

THE USE AND ABUSE OF ANTIPYRETICS IN SEPTIC FEVERS.

IN former years when pathology as a science was still unknown, the treatment of disease was largely empirical and symptomatic. Long lists of recorded facts were employed, not as they should have been then, and are now, merely to prove the nature of certain chemical discoveries and therapeutical applications in relation to disease; but in a haphazard sort of a way. The lines of treatment themselves were based thereupon, ofttimes without reason or scientific deduction. If new diseases made their appearance the only thing that could have been done in those days was to combat the accompanying symptoms regardless of the original seat of the trouble. A fever had to be put down, whether it depended upon a peritonitis or a pneumonia; a headache had to be treated with anodynes, whether it were caused by eye-strain or disordered stomach; syncope was a condition that called for blood-letting, whether the cause were anæmia or hyperæmia of the brain. Occasionally excellent results were obtained by this uncertain, irrational method of treatment. Indeed, medicine is not yet sufficiently advanced as a science, perhaps never will be, for us to discard empiricism entirely.

Pathology is teaching new facts every day in regard to the unseen causes of the symptoms which the older practitioners had to combat thus blindly. Microbes, bacteria and ptomaines have put quite a new face upon many diseases, and instead of attacking the symptoms, we devote all our energies to destroying the noxious germs; the former we allow to take care of themselves. We have every reason to be justly proud of these later discoveries in medicine, but in our enthusiasm there is danger of our being too radical, particularly as we are in the dark still with regard to many of the diseases.

In no department of therapeutics are the conservative and radical methods so pronounced or so widely opposed to each other as in the treatment of the fevers. One class of men, following the lead of Semmola, would never give antipyretics in a case of typhoid. They believe that the high temperature is of no consequence whatever, so that the intestinal lesion with its bacteria receives the appropriate attention. Some even go so far as to assert that the fever is rather an advantage than otherwise, being nature's germicide or means of destroying the deleterious products in the alimentary canal. In some of the hospitals nothing but a tonic and stimulative treatment is administered. In others an intestinal antiseptic is given and the patient merely placed under the most comfortable and best hygienic conditions. These radical methods do not include such drugs as quinine, antipyrin, phenacetin, and the rest of the phenol group; yet most excellent results are attained.

On the other hand there are those who believe literally in the self-limitation of typhoid, and in the absolute uselessness of attempting to abort the affection itself. They teach that the fatality of the disease, irrespective of such accidents as perforation and hemorrhage, is dependent upon the extreme exhaustion caused by the intense fever. A high temperature, besides being an indication of rapid destruction of tissues, is itself a powerful cause of such distinctive changes. Hence, the appropriate treat-

ment would be to support the patient and keep down the temperature until the disease had run its course.

We believe that both of these views are extreme. In some cases the happiest results will be obtained by the application of either of these methods of treatment; but to limit oneself to either, in all cases, would be dangerous, unscientific and irrational. The disease is a germ disease; therefore, first of all, we must, if possible, destroy the parasites in the alimentary canal. Various antiseptics have been recommended for this purpose, such as the sulpho-carbolate of zinc and the iodine and carbolic acid mixture. In using the former we need rarely administer antipyretics as the action of the antiseptic as such produces an antipyretic effect itself.

By intestinal antisepsis we do not mean the destruction of the typhoid bacilli in the intestines, for it has been shown that at a very early period in the disease these organisms have penetrated beyond the alimentary tract and can be found in the blood. But it is probable that the symptoms which go to make up a typical case of typhoid fever depend upon a complexity of causes; of which the typhoid bacillus is only the first one, which opens the door to the others. Suppurations are due to the staphylococcus aureus, etc., which attack the Peyer's patches when weakened by the assaults of the typhoid bacteria. Part of the fever, all of the delirium, tympanites, diarrhœa, coma-vigil, and many other symptoms, are due to the absorption into the blood of ptomaines generated in the intestinal canal, by the action of, perhaps, a number of diverse bacteria; scarcely any of the characteristic symptoms of typhoid fever being really due to Klebs' bacillus, as they disappear when intestinal asepsis has been secured. In fact, if we wish to obtain a clinical picture of the effects produced by the typhoid bacillus pure and simple, we must eliminate the results of the operations of that malefic laboratory which is established in the alimentary canal, amid its dead and dying tissues and the decomposing secretions and substances given as food. This may be done most readily by giving the sulpho-carbolate of zinc until the stools become inodorous.

A high temperature is certainly a cause of extreme exhaustion, and in some cases, therefore, prompt and efficient antipyretics must be administered along with the special treatment. From this standpoint these antipyretics are really tonics, the same as the alcoholic stimulants when they are administered in extreme adynamic cases, to supply the material whereon the fever may feed, and thus allow the already vitiated tissues to remain untouched. Hence, in many cases a judicious use of the antipyretics together with the antiseptics is called for. The choice of the antipyretic seems to be largely a personal one among clinicians.

We have employed all of the more prominent ones and are emphatic in giving our preference generally to antifebrin, administered not so much by dose as by the effect produced. An unpleasant degree of cyanosis and depression is sometimes caused by antifebrin, but while these effects are not common, if the drug be administered merely in such amounts as to moderate the fever without pulling it down to the normal point, they are not of any very serious consequence. In certain cases where there are not marked counter-indications, especially in young people, we have found large doses of quinine with a small quantity of opium, given in suppository, an efficient means of lowering the temperature. We have had most unpleasant effects upon the nervous system from the use of antipyrin, and hence we rarely use it in typhoid cases. Phenacetin will sometimes accomplish most happily what none of the rest of the same group will.

It is our conclusion then that in the treatment of the septic fevers, while the main object should be to destroy the source of the disease, the germs, our next care should be to attend to the support and comfort of the patient, chief among the means of which will be the regulating of the temperature.

THE STUDY OF MEDICINE.

ACCORDING to all indications, the coming winter will see a larger number of men beginning the study of medicine than ever. In our own city the list of matriculants at all the colleges is far larger than that of previous years. Doubtless one of the causes for this is the coming three years course, which, though adopted already by some of the colleges, will not be compulsory until after 1890 in others. It is a general impression, even among the laity, that the profession is overcrowded; hence, it may be pertinently asked why do so many men seek to enter it? In making his selection of a profession, the student is probably more immediately influenced by the thought that it will be the most congenial method of earning a livelihood. He imagines that the life will be a leisurely one, the income abundant, and the chances for renown greater than in any other calling. A small minority may be altruistic enough to study medicine for the purpose of helping their suffering fellow-creatures.

A rapidly rising young surgeon of London once said to us that he thought no man ought ever to enter the medical profession who had not a fortune or other outside means of support. He believed that science, particularly the science of medicine, could be successfully pursued only by those who were perfectly free to follow their tastes, and who were unhampered by the cares of money getting. Doubtless our English cousin is right if the pursuit of pure science be the object and the student be the fortunate possessor of indominate energy. But when we gently remonstrated with him by pointing out that the Galileos, Davys, and Watts of science were all poor boys, and when we, furthermore, hinted that possibly poverty and humanity themselves were powerful stimulants to a capable and ambitious lad, he admitted that the latter view of the question was suf-

ficient to make him modify his first statement somewhat. There are young men of means and leisure continually entering upon the study of medicine that have not the least liking for any of the other occupations in life. Hence, there are other influences besides those already mentioned at work impelling them into the study of the medical sciences. As a mere accomplishment, the knowledge afforded by the medical curriculum has been sought after by some of the world's brightest intellects. Men who have never had a thought of practising have nevertheless attended medical courses of lectures, and men who have purposed devoting themselves to other arts and sciences have considered it necessary to take a preliminary course in medicine. Nothing is so interesting to man as man, and wherever the human intellect pries, whether in the world of matter or of spirit, it comes in contact with what has close relation to man. The very subject, therefore, that heads the list of medical studies, that which is of the very first importance, human anatomy, is of itself sufficient to attract the attention of those searching for an interesting subject of thought. Many love the science in the abstract, but have not the hardihood to study it in the dissecting-room or beside the operating-table. A physician used to be one who studied physics, including pretty nearly all the sciences. Botany, chemistry, mathematics, and even the allied sciences of biology and geology—altogether the most attractive group of studies—are more or less included in his investigations. In days gone by even a knowledge of astronomy, under the debased form of astrology, was demanded of him. As to the metaphysical sciences, no one can be perfect in them without a knowledge of medicine, and a physician who wishes to possess all the resources of his art will do well to be somewhat acquainted with them.

After the student has entered upon his medical course, the scientific turn of mind which is gradually developed in him stimulates him to a greater degree of study, and makes him fonder than ever of this most fascinating department of science. Thus, his intellect, like a shuttlecock, is made to vibrate between the two powerful influences, its own developing love for science itself, and the abundant food for thought and research in its chosen department. He becomes a skeptic in the best sense of the term, taking nothing upon authority that he can investigate for himself. As he advances in his researches, he acquires a feeling of reverence and awe for the "one temple in the universe, which is the body of man," and he imagines that he "touches heaven when he lays his hands upon a human body." The mystery of the *how*, *whence*, *whither*, and *why* of it all fascinates and goads him on to even more strenuous exertions. All departments of human thought and activity, art, literature, and science are grappled in the endeavor to solve the mystery. Sometimes becoming dissatisfied with the mere routine of a practitioner's life, or more often finding the powers of mind too small to compass all knowledge, the student turns to other neighboring fields and cultivates them. It is in this way that nearly all of our greatest scientists and thinkers of the world have at some time in the course of their lives, most frequently the beginning of it, been enrolled as students of medicine.

There is a tendency on the part of some, and we fear they are usually the unsuccessful, jealous rivals, to discourage young men entering upon the study of medicine. This is an error. If a lad shows the slightest disposition to enter the temple of science, medicine is the very best portal through which he can pass. If, however, after starting upon his course, he is determined still to practise the art of curing his fellow-beings, closer restrictions should be thrown about him; he should be examined as to his fitness in this special kind of work, and every precaution taken to protect the people against ignorance and incapability. So we are glad to see this influx of students to our great medical schools; at the same time, we have wished that a perfect and satisfactory examining board, free from prejudice and political influences, had been established, with full power to prevent any one practising medicine who is not by aptitude and training fit for it.

Annotations.

ONE of our Western contemporaries evidently believes that a journal cannot be practical and at the same time scientific.

The word "scientific" has a somewhat different meaning in the minds of different persons. To some, an article is not truly scientific unless it is emasculated by leaving out everything which can possibly be made useful, and in which every sentence can be fortified by quotations from German authorities. Why such a paper should be considered more worthy than a well-written record of clincal studies, or a well-founded deduction from experience in the therapeutics of a disease, we are unable to comprehend. Nor do we readily see why a journal should be considered worthy only when it caters to that very limited class which, having access to the great medical libraries and the city societies, has neither the need nor the desire for any journal. There are journals of physiology for those who are interested in physiological research; the specialist has his organs in great plenty; the bacteriologist has his *Centralblatt*; why, then, should the organ of the great mass of the profession, giving an epitome of the medical thought of the day, be looked down upon? Simply because this part of the profession is itself looked down upon, by these men whose little sum of medical art would go but a short distance in furnishing the stock of the family physician. We see about us men dying of curable disease; men who might be saved were their medical attendants better educated, better skilled, and more earnest in their duties. There is not one man living who holds in his head the sum of all human knowledge of the medical art. There are

thousands of workers who are earnest in their desire to be useful, who, through ignorance, are daily solving problems which have already been solved over and over again, for ages past. What a waste would be saved were each to know what his predecessors had done, what experiments they had made, and into what errors they had tumbled. In so much as we can assist in this work of disseminating knowledge and recording experiences, we are satisfied to be useful, and willingly leave our friends to the pursuit of what they denominate science, but which reminds us rather of the Byzantine Greeks, who discussed the question of how many angels could dance on the point of a needle, while the barbarians were dismembering their empire and closing in on their doomed capital.

RUSSIA'S WORKING CLASSES.

THE condition of a large part of the working class in our own country is bad enough—too bad, we all know—but compared with the lot of the same class in Russia, our working people's lives are enviable.

At the late International Congress of Hygiene, at Paris, Madame Tkatcheff read a highly interesting paper on the Condition of the Working Classes in Russia.

There are some 932,000 operatives employed in the various mills and factories of Russia. Many of these are agriculturists, who, being unable to make a living from the soil, work in a factory from September to February. These have no homes in the town or city they come to, but sleep in the factory. Men, women, and children are thrown together in crowded, ill-smelling rooms; the result being, as we may expect, a high death-rate and a shocking immorality. The migrations of villagers into towns for a short time each year brought back syphilis, and some of the villages were infected to such an extent that every single inhabitant had this disease.

The special death-rate of the working class is not known, but compare the general death-rate with that of other countries: Sweden, 17 per 1000; France, 24 per 1000; Russia, 36.8 per 1000.

Most of these laborers are not able to afford leather boots, but wrap their feet in paper and rags, and thrust them into wooden shoes. A shirt is an unknown luxury. To keep himself from freezing, the peasant wears a rough garment of sheepskin, with the wool inside. The hours of work vary from twelve to fourteen. We have not space for more details. They are all of wretchedness. What a field for philanthropic exertions.

HEARING and reading an author's remarks will ofttimes lead to different impressions. By one of these fatalities, the result of not an unnatural inference drawn from Brush's statements made before the Section of Pædiatrics, an incorrect annotation appeared in the DIETETIC GAZETTE of July 13. Dr. Brush did not intend to say that by breeding cattle the milk could be made to approach in composition that of the human female. He holds that milk may be divided into two distinct varieties, according as it is the product of the *cud-chewing* or the *non-cud-chewing* animals. This is an important limitation. The former variety afforded by the cow contains a kind of caseine, which coagulates into a hard mass under the action of the digestive ferment. The latter —that given by the non-cud-chewing animals, to which the human race belongs—does not, under the action of rennet or acids, coagulate into the hard mass we find in cow's milk, but into smaller, granular, or flocculent masses, easily digestible. In regard to the breeding of cows, no thought is taken of attempting to transform a cud-chewing into a non-cud-chewing animal, but they should be bred solely for health and not for commercial value in producing quantities of milk. If this is done the best of all foods for the infant will be obtained, aside from the mother's own milk.

WHAT nonsense is the talk of a medical journal sacrificing the interests of its readers to those of its advertisers. No journal could live which was managed upon such principles, and the first to desert it would be the advertisers themselves. We have found no body of men more keenly alive than they to the value of the professional standing of journals, placing it above that of circulation. Even the journals which are founded and supported by publishing or manufacturing houses find it necessary to be exceedingly careful in dealing with their proprietor's interests; anything like an effort to push them being disastrous. Even when such favoritism is limited simply to the benign view taken of the firm's own books, it is enough to constitute an obstacle to the success of the journal. Experience has repeatedly shown that when such journals have been withdrawn completely from the control of the publishers, they have quickly won a popularity which the best editing and the most lavish expenditure for material previously failed to secure.

It is the reader whose interests must be considered, first and last; and unless this is the ruling principle of a journal, it will never win the support of the profession, which constitutes its true value. If it sinks to be the mouthpiece of a publishing house or an advertising touter, a blackmailer, or a means for the dissemination of its editor's personal views, it fails to be an organ of the profession. The representative of one man is but a paltry affair; the representative of many men wears a dignity derived from the sum of all its constituents.

WE learn from the *Journal d' Hygiene* that cholera is assuming a threatening attitude in Mesopotamia. Confined to the southern part of the Province during the first days of August, in a triangular section between Bassorah and Rumlyta, the epidemic has ascended the Tigris rapidly and appeared at Bagdad, on August 14. By August 29, all the intervening territory was affected, and the disease had spread north to Hanejuine. The banks of the Euphrates from Rosma to Mussayeb are also attacked. Bagdad is in desolation, almost abandoned; the inhabitants camping in the environs. On August 25, there were registered one hundred deaths, of which ninety-three were from cholera.

Letters to the Editor.

A CASE OF SENILE GANGRENE.

RHODA IVEY, aged eighty-one, was attacked some time in March, 1889, with a severe pain in the toe next to the great toe on the left foot.

Pain, without swelling or fever, continued for several weeks, when the great toe, together with the other toes on the same foot, became involved, causing her unceasing and almost unbearable pain, notwithstanding the free use of anodynes.

About the time the other toes began to become involved, the toe first attacked gave evident signs of approaching death, by shriveling and turning a mouldy black.

The diagnosis of senile gangrene, which disease had all along been suspected, was now confirmed. Notwithstanding the great pain and much restlessness there was no fever; the temperature remaining a little subnormal; no redness; no swelling, and not much soreness upon pressure. The pulse, however, was very small, highly compressible, occasionally intermitting and quite frequent, varying from 110 to 120 per minute.

All along the woman retained a remarkably fine appetite. She would exclaim: "Yes, doctor, I can eat anything they will bring me."

Gangrene progressed slowly until about the first of August, when a line of demarcation was very irregularly but distinctly formed around the foot near the instep. Notwithstanding her great age and feeblenes, it was now deemed best to amputate.

This the writer, aided by one regular physician and a druggist, did, on August 10, cutting a little below the knee-joint, or about the union of the upper and middle third of the tibia.

So far the writer has reported nothing very unusual or remarkable in a case of senile gangrene. It was noticed, when the cutaneous and subcutaneous tissues were being divided, that only a very little, very black, thin, water-like blood escaped.

The writer finding it somewhat difficult to find the main arteries—the posterior tibial, and the peroneal—for ligation, had the tourniquet loosened, when to our surprise no blood flowed.

We removed the tourniquet entirely and rubbed the limb downward, but not a teaspoonful of blood could we make to flow, the flesh on the stump looking as bloodless as a piece of steak in the market. We decided not to cut above the knee; and completed the operation without applying a ligature!

The woman recovered promptly and fully from the influence of the anæsthetic, chloroform, and lived three days and thirteen hours, retaining all the while her mental faculties unimpaired until within six hours of her decease.

A little fever set in during the morning of the third day and ran very high just before death, the temperature rising a little above 106° F.

At no time during the three days was the dressing about the stump more than slightly stained with blood.

Can you explain the cause, Mr. Editor, of the exsanguineous condition of the limb?

Could there have been an obstruction within the popliteal or femoral somewhere along its course? Could a thrombus have caused it?

Could a hypertrophy or thickened condition of the walls of the artery somewhere along its track, or throughout its entirety, have occluded the free circulation?

If such a condition existed, how could the warmth and nutrition of the limb be sustained, above the line of demarcation?

Could a greatly enfeebled condition of the *heart* explain this bloodlessness of the leg?

We had no opportunity of examining the veins and arteries of the amputated part, nor were we allowed an autopsy.

There was no history of a traumatism involving any part of the limb. The urine was normal—at least, there existed no glycosuria. The right foot and leg seemed to be in a normal condition. The pulsation in its arteries could be distinctly felt as low down as the instep. This was not the case with the diseased limb. We could not discover any pulsation anywhere, even as high up as the beginning of the femoral.

Dr. C. S. Kendrick and Mr. Geo. W. Brown, druggist, both of Sharon, assisted the writer in the above operation.

ARTHUR C. DAVIDSON, M.D.

SHARON, GA.

[The artery was occluded above the point at which the amputation was performed; probably above the crural ring. The occlusion was probably due to embolism, as the history shows that the obstruction was not sudden or complete at first. An embolic mass has been washed into the arterial circulation, or, more probably, a deposit of fibrin took place at the bifurcation of the iliac; and as it grew larger by accretion, the obstruction to the circulation gave rise to the gangrene. In the upper part of the limb a collateral circulation was sufficiently established to preserve the vitality of the tissues; and this is itself singular, in a woman of such advanced age.]

SCHOOL HYGIENE.

YOUR editorial, entitled, The Care of the Children, comes not any too soon. While we have very many most worthy persons engaged in the work of teaching, unfortunately we encounter occasionally a specimen utterly unfit to have charge even of a brute, let alone a growing child, whose constitution is in process of formation, whose future may be made or marred according as it may please the person who is for the time being placed over it in *loco parentis*. So many times have I been called to prescribe for the results of the unthinking, even unfeeling, treatment to which children have been subjected by their teachers, that I have felt it my duty to do what I could to prevent a repetition of what in some is true barbarism, while in others it arises from carelessness or want of attention to the physical condition of the little ones under their orders.

I do not now propose to talk of ill ventilated school rooms, and the like crying evils, which our excellent Board of Health, in the person of the Medical In-

spector, is earnestly endeavoring to lessen. I desire to direct special attention to class-room discipline.

You say "a certain amount of leniency must be admitted." This is of vast importance. When we remember that many young persons are compelled to answer the calls of nature suddenly, in some cases almost without warning, what rule can be adopted by which all are to be governed? In fact, I now recall a case. A sensitive girl, just at puberty, suffering with the diarrhœa of incipient phthisis, not being permitted to retire at her urgent request, having soiled herself and clothing, was brutally placed on the platform, and the entire class informed why, and the suggestion made that she needed to return to the use of diapers. Can we wonder that she brooded over this outrageous insult to her budding womanhood, and could not be induced to risk another such scene?

Or, in reply to the anxious request for permission to retire, the reply is, "you shall take so many marks for going."

I might add many other examples which have been brought to my knowledge, where such a person seemed insensible to any remonstrance or mode of reasoning, although the parents have carefully explained the conditions surrounding their child, and begged for that leniency as an especial favor.

As I write, memory recalls the many instances where children have been compelled to submit rather than have the teacher "down on them." In my study of the diseases of children for the many years which I have devoted to these interesting members of society, I have frequently been led to admire how much nature can do to enable them to overcome the injuries inflicted upon them in early life, and to be glad to find the small amount of harm done by treatment the most brutal. You say, "Girls, for instance, are sometimes subject to weakness for which they must retire more frequently than usual. To disregard such a condition might lead to lifelong misery and ill health." Undoubtedly much of the troubles incident to the approach of puberty are, in a great degree, due to the proper care having been wanting at this crisis of their lives. Mothers need to guard against the evils thus likely to be induced, and to see that the calls of nature are properly heeded. I have often thought that a great good might be accomplished if we had a board of lady visitors for every school, composed wholly of "mothers," who would, from the care of their own darlings, know the wants of other people's children, and thus be ready to interpose at the proper time. In many cases it would seem as though children at the ordinary schools were like sailors on board ship, solely at the mercy of the captain, who is judge, jury, and executioner, and holds the lives of the sailors at his command, and when in port difficult to punish.

By all means let us have a jury of matrons, who shall decide when a teacher of girls shall change her treatment and make it in accordance with common sense and good hygiene.

Some day I shall endeavor to give you some clinical cases illustrative of the evils occurring from the causes alluded to.

Wm. B. Atkinson, M.D.
Philadelphia, Sept. 14, 1889.

SULPHO-CARBOLATE OF ZINC IN DIARRHŒA.

My experience with the sulpho-carbolate of zinc has been very limited, but, so far as it goes, exceedingly satisfactory. The first case in which I used it was that of a child, Robert T., aged eighteen months; who, for ten days, had been suffering from a severe attack of summer diarrhœa. The little fellow, when I first saw him, had fallen away to almost a shadow of his former self; his features were pinched, and he suffered severe pain with every movement from the bowels, which movements occurred once or twice every hour, day and night. The evacuations were of a very offensive odor, and at times contained a little blood. He was unable to retain anything on the stomach; not even milk and limewater, or any prepared food, of which latter his nurse had tried many varieties. He had been under the care of a so-called homœopath for a week before I saw him, from which fact I infer that we may exclude the possibility of any medicinal influence on the course of the disease up to that time. I immediately placed the little one on half-grain doses of the sulpho-carbolate in combination with one grain of the subnitrate of bismuth, every hour, until improvement should be manifest. This course was continued until eight powders were taken, when the improvement was so marked that we dropped down to one dose every two hours, and, in twenty-four hours more, the child seemed like a different being—diarrhœa thoroughly under control, no vomiting, and but slight pain. This rapid improvement continued, until, at the end of three days more, I dismissed the case. Of course, the feeding was carefully regulated, but it was also attended to with much intelligence by my predecessor.

My second case was that of a young lady whom I saw five days later (August 10), who was suffering from subacute ileo-colitis. Her I placed on three-grain doses of sulpho-carbolate of zinc in combination with an equal quantity of subnitrate of bismuth and one grain of bicarbonate of soda every two hours. The recovery was prompt and permanent. Since then I have had a few more cases, mostly young children of poor parents, whom I was happy to treat, rather as affording material for observing the action of the drug than as a matter of business, and I can heartily testify to its decided therapeutic value, when applied to the class of cases in which a powerful, yet harmless, agent is required to bring about a comparatively aseptic condition in the intestinal tract.

Martin Rively, M.D.
2300 Green Street.

A Singular Error in Diagnosticating a Breech Presentation.—Koviot describes a case of breech presentation in a primipara forty years old, in which the os uteri, but slightly dilated, was thought to be the child's anus, as it was smeared with meconium. Dilatation was thought complete when it had scarcely begun. The child was stillborn, after a tedious labor, during which the error became apparent to the obstetricians in attendance.

—*American Jour. of Med. Sci.*

Cincinnati Letter.

THE colleges, clinics, societies, and medical matters in general, are looking up. Many of the doctors who have been away during the summer have returned and again taken up the prescription blank. The poor doctor who staid at home seems to look as well as his brother who haunted health resorts. Cincinnati has been remarkably comfortable during the past summer.

A death from chloroform is again added to the list in Cincinnati. The unfortunate patient was a young man aged thirty-two, who was suffering from a crushed thumb. He applied to his physician, who readily told him that an amputation was necessary. To this the patient agreed. The doctor called in another physician to assist him, who gave the chloroform, which was done at the patient's house. Hardly a teaspoonful of the anæsthetic had been given when the patient was taken with convulsions and died almost instantly. Both physicians labored for more than an hour to resuscitate the man, but all to no purpose. Death was due to paralysis of the heart.

The Cincinnati Hospital, while one of the most careful, economical, and scientifically managed institutions of its kind in the country, is just now, and has been for the past few months, subjected to a series of persecutions which are abominable. The outs are howling for reform, and the truth is, they are only wanting a chance at the perquisites themselves. One of the daily papers has been fighting the recently appointed Superintendent ever since his appointment, although he had been an efficient and trusty officer of the institution for many years. Recently an expert bookkeeper has been engaged to unearth matters, and while he may be very expert as a bookkeeper, in many other things concerning hospital management he has proven himself rather pert than expert. While advising retrenchment, economy, and reform, he criticizes the fact that externes are required to attend the Hospital six months before becoming internes, and live outside of the Hospital at their own expense. He thinks this excludes poorer students and those residing at a distance from competing. How much economy is there in feeding, bedding, and lodging six wild medical students for six months? He criticizes the fact, that while the librarian was formerly paid out of the library fund, he is now paid from the general fund. Had he inquired further he would have learned that a former employé of the Hospital has added to his former duties that of librarian, which position is filled better than it has ever been done before. He thinks it improper that a library for the sole use of physicians should be placed in a building built by general taxation. He queries, why not place this library in the public library? The answer is that it would be far less accessible, as far as the books were concerned, and as to the journals, they would be placed in the periodical room, which is so crowded with tramps and vagabonds that no physician would be comfortable, and scarcely safe, to read them. He cites the fact that there were no patients in the branch hospital for contagious diseases during 1888, and but one during 1887, yet two persons were paid for attendance there. He also wants to know why this farm of fifty acres does not help produce the food used in the Hospital? Were he as good a farmer as bookkeeper, he would know that a farm of fifty acres left untenanted in the vicinity of Cincinnati would soon go to rack and ruin, and had he made inquiries, he would have found that this farm of fifty acres did contribute very substantially to the feeding of the inmates of the Hospital.

A certain preacher, who has his church arranged like a theatre, who appears in the pulpit in a dress suit and patent leather pumps, and who is strictly sensational in his style, is interesting himself very much in the starting of a new free hospital for women. This patent-leather preacher, who would be called a quack if he were a saver of bodies instead of souls, goes about telling admiring audiences of the terrible high per cent. of mortality in the Cincinnati Hospital in laparotomies. He, or his medical supply, runs the statistics back twenty-one years, to the time when abdominal section was made here by the general surgeon, in the surgical wards, with no fear of erysipelas or thought of antiseptics. The statistics of the Cincinnati Hospital for the few years past in this line are excellent, and it is very unfair to have a preacher and a lot of sympathetic women running about decrying the abdominal surgery of twenty-one years ago.

Book Reviews.

THE NERVO-VASCULAR SYSTEM. Three charts arranged by W. HENRY PRICE and S. POTTS EAGLETON, and examined and approved by JOHN B. DEAVER, M.D., Demonstrator of Anatomy, University of Pennsylvania. Part I, the Nerves; Part II, the Arteries; Part III, the Veins. Philadelphia: F. A. Davis, 1889.

We have examined these charts and find them very well arranged, but of what use they will be to anybody we fail to comprehend. Charts upon anatomical subjects are continually being published, and, perhaps, as a kind of remembrance, when hung upon the walls of the dissecting room, may have some infinitesimal value. In themselves, they are but a tiresome list of names. To the inquiring student, or to the referring physician, they will simply be a test of how good a memory he has for retaining names. As for information, they do not afford even so much as a compend, which usually offers little enough.

THE FEDERAL GOVERNMENT OF SWITZERLAND; an Essay on the Constitution. By BERNARD MOSES, Ph.D., Professor of History and Political Economy, University of California. Cloth, pp. 256. Price, $1.50. San Francisco: Pacific Publishing Co., 1889.

It is becoming quite a common thing for physicians to take their recreation in traveling through Europe, and even to spend weeks and months at some of the more popular foreign resorts. Among all the countries none can compare with Switzerland for magnificent scenery and general education of the people. The land of Tell and Zwingle will ever be dear to the people of the United States, as there dawned and flour-

ished, when all Europe was ground down by feudalism, that free and liberal form of government of which Plato and Sir Thomas More dreamed, and of which we, the citizens of the United States, enjoy the most happy realization. The volume whose title we give above is an excellent exposé of the development and present condition of the Swiss Government. We are sure that physicians who have traveled already, and those who anticipate traveling amongst this remarkable people, will find pleasure and instruction in reading of their form of government.

FIBROMES UTERINS, leur traitement par l'electrolyse (methode Apostoli) et leur élimination fréquente sous-muqueuse par l'action de l'électricité, par le docteur La Torre (de Rome). Extract, revu et augmenté, des *Archives de Tocologie*, Dec., 1888, Jan. Fev., 1889. Paris: O. Doin, 1889.

DU TRAITEMENT DES FIBROMES UTERINS, par la Methode d'Apostoli (l'electrolyse uterine) avec une lettre-préface du Dr. Apostoli, par le Dr. Delétang (de Nantes). Paris: O. Doin, 1889.

These two brochures are especially timely, now that the question of electrolysis in the treatment of uterine fibroids is being so vigorously agitated. Many of the Tait school of operators find no good in the treatment whatever; those of the opposite extreme frequently claim results that are entirely incredible. Like every new advance in medical treatment the happy mean is apt to be the most nearly correct. Before resorting to the more serious operation, it is well to test the effects of electrolysis; sometimes the results are only an amelioration of symptoms, and at other times there is a decided reduction in the size of the tumor. Without being over-enthusiastic, the authors cite cases and report favorably upon the use of electricity in fibroids. Both essays contain quite complete descriptions of the methods of application, *modus operandi*, and ultimate results of the treatment.

SYPHILIS OF THE NERVOUS SYSTEM. By H. C. WOOD, M.D., LL.D., Physicians' Leisure Library; paper 25 cents; cloth 50 cents; pp. 135, illustrated. Detroit: Geo. S. Davis, 1889.

In this brochure the author has handled in a very readable and practical manner a comparatively obscure department of neurology. When the syphilitic affections of the nerve-centers are at all amenable to treatment, the results obtained are usually most gratifying. The use of the mercurials and iodides usually gives complete and satisfactory relief when they make any impression whatever. Nevertheless, the subject is an obscure one, as evidenced by how little we know of its pathology, and by the large variety of nervous manifestations of a pathological character that are attributed to syphilitic infection. The major part of the present essay is devoted to syphilis of the brain, as comparatively nothing is known of the disease in connection with the spinal cord and peripheral nerves. The writer's remarks in regard to the hereditary character of these diseases are particularly interesting. The experience of foreign practitioners and his own are the basis of his ideas almost entirely, and though there is nothing particularly original about them, they are put in a manner that is both terse and convincing.

We must offer a word in regard to the appearance of the publication. We have often wondered why scientific books, particularly the smaller ones, should be doomed always to a plain, unattractive cover. The publishers of novels have learned that the outside appearance of a book induces one to purchase it, or if lying upon the table to pick it up to read. This may be considered a puerile matter in regard to scientific works, but we feel certain from what we have observed that to one of an artistic bent of mind an attractive, decorated cover is not a small item in the pleasure, and consequently more lasting instruction, derived from the work.

We have often desired an opportunity to make this suggestion to publishers of the smaller medical books, and we have taken this present volume with its prettily decorated, gilded, morocco cover and clean, open pages as the appropriate occasion.

The Medical Digest.

CHLORIDE of ammonium, a half drachm in water, is said to quickly dissipate drunkenness.

ARSENICAL wall paper is recommended as an application to the walls of houses in malarious districts.

THREE grains of chloral to an ounce of glycerin is recommended as an efficient remedy in early quinsy. It is probable that the glycerin is the efficient agent; and that guaiac is a better remedy.

JUGULATING PNEUMONIA.—At the recent Therapeutical Congress, in Paris, M. Petrescü, of Bukharest, claimed that pneumonia could be aborted in its early stages by giving large doses of digitalis, *e. g.*, four to eight grammes (ʒj to ʒij) of the leaves in infusion, daily.

DR. A. BOWIE reports two cases of cardiac failure in which death seemed imminent, that were speedily relieved by small doses of the tincture of nux vomica every half hour, for four doses, then every hour. He considers it the most valuable remedy that we have. —*London Lancet.*

A BACTERIOLOGICAL PRIZE.—The Vermont Microscopical Association offers a prize of two hundred and fifty dollars, on behalf of the Wells and Richardson Company, to the "first discoverer of a new disease germ." The conditions may be learnt by communicating with C. Smith Boynton, M.D., Secretary of the Association, Burlington, Vermont, U. S. A.

TUBERCULOUS INFECTION THROUGH EAR-RINGS. A case is related in the *Wiener medizinische Presse* of a young girl, fourteen years of age, of a perfectly healthy family, who wore ear-rings left to her by a friend who had died of pulmonary tuberculosis. Soon ulcers appeared on the lobes of both ears, the cervical lymph-nodules became swollen, and percussion revealed dulness at the apex of the left lung. Tubercle bacilli were found in the ulcers and in the sputa. It was presumed that the ear-rings were the agents of infection.—N. Y. *Med. Record.*

Ergot in Childbed.—Dr. Pinzoni, of Bologna, has made some interesting clinical experiments in order to determine with something like precision the value of ergot in childbed. He administered ergot systematically to ninety-one lying-in patients, generally in the form of about two grammes of the powder daily. Seventy-nine similar cases were treated without ergot. After comparing the series, he came to the following conclusions:—Ergot has little or no influence on the temperature, at the most a slight rise is occasionally observed. It hastens the pulse a little, yet has no marked influence on the physiological slackening of the pulse observed during the first days after delivery. The physiological increase in the secretion of urine during the first days is favored by ergot. The involution of the uterus, according to Dr. Pinzoni's researches, is either totally uninfluenced by ergot, or slightly retarded. The escape of the lochia remains normal when that drug is given; but clots, as universal experience has proved, are more readily expelled. The lochia seldom smell fœtid when the ergot is taken. Ergot delays the after-pains in primiparæ, and lessens them when they have already commenced. The secretion of milk is retarded and lessened by ergot, and sometimes completely suppressed. Ergot seems, in the belief of Dr. Pinzoni, to be a prophylactic against puerperal fever, an indirect antiseptic agent. When infection has already taken place, ergot appears, on the other hand, to hasten the entrance of the virus into the circulation. Dr. Pinzoni's researches appeared in the *Bollettino delle Scienze med. Bologna*, series VI, vol. XX.—*Brit. Med. Jour.*

Modifications of Egg-Albumen.—A Russian medical man discovered some time since that the eggs of various species of birds contained different kinds of albumen. For instance, the eggs of birds which are born naked, blind, and incapable of cöordinate movement, contain an albumen which remains transparent after coagulation by heat, and readily imbibes water, becoming swollen and very easily digestible. This transparent albumen is called *tata*, and is much used in some countries in feeding the sick. The eggs must be fresh, for in the course of a day, if left in contact with the yolk, the albumen is changed into ordinary albumen and becomes opaque on boiling. The most interesting and practical feature of these observations lies in the discovery that if fowls' eggs in their shells are treated with caustic-potash or soda the albumen is converted into this transparent variety. Thus modified, the product may be dried and powdered, and keeps good for years. It contains 13 per cent. of nitrogen, and in water swells up to twenty-five times its original volume. It is quite tasteless, and can, therefore, be mixed with chocolate, coffee, &c., without detriment to their quality, or may be made into gruel or added to beef tea. Moreover, the gelatinous mass which results can be readily made into jellies and suitably flavored. The powder has been tried extensively in Russia both on the healthy and the sick, and appears to have proved very satisfactory. As the mode of preparation is simple, *tata* would appear to constitute a valuable addition to the dietary of the sick and ailing.—*Medical Press and Circular.*

A Case of Resection of the Rib and Pleura, for an Osteochondroma of the Rib.—P. Riesenfeld, of Hamburg, reports the following interesting case which was operated on by Dr. Alsberg, in the Jewish Hospital of Hamburg, in July, 1888, when a portion of a rib and a piece of the pleura about the size of a silver dollar were removed on account of a new growth: The patient, a female, aged twenty-two years, was admitted to the hospital July 16, 1888. Previous history good. In April, 1888, patient noticed on the left side of chest a small swelling about the size of a walnut, which swelling steadily increased in size, but caused no pain or interference with the general health.

Examination shows a delicate woman. On the left side of the thorax, on the eighth rib between the anterior and middle axillary line, is a tumor which reaches above into the seventh and below into the eighth intercostal space. This tumor is about the size of a goose egg, and is hard and immovable; its surface is smooth in some parts and roughened in others. The skin over the tumor is freely movable and not painful on pressure.

The operation was performed on July 15. Flaps consisting of skin and muscular tissue were made, and the eighth and ninth ribs exposed. It was then seen that the tumor surrounded the eighth rib. The periosteum over the eighth rib was dissected away for a distance of five centimeters in front and behind the tumor, and the bone was then cut through. The tumor was found to be adherent to the pleura, and a portion of the latter had to be cut away, and air entered into the chest cavity.

The pleural sac was not washed out. The wound was closed by deep and superficial sutures, a strip of iodoform gauze having previously been inserted at its lower angle so as to insure drainage. An iodoform gauze and moss dressing was then applied. The pulse remained good throughout the operation.

The evening of the operation the patient complained of dyspnœa, which increased steadily, and was followed by a cough on the second day. The evening of the third day the temperature rose to 38.6° C., and the pulse to 140, but this rapidly subsided under proper therapeutic measures, and from the sixth day the pulse, temperature, and respiration were normal.

On the fourth day the dressing was changed and the strip of iodoform gauze replaced by a drainage-tube, which was removed on the tenth day.

In four weeks the patient left the hospital completely cured, the lung having completely expanded again.

Up to the time of writing, *i. e.*, six months later, there is no return of the disease.

Microscopical examination of the tumor showed it to be an osteochondroma, and in one place there was some mucous tissue.

The author has only been able to collect in literature sixteen cases where the rib and pleura were resected on account of new growths. Five of these cases terminated fatally. *Deutsche Medicinische Wochenschrift—Annals of Surgery.*

The University of the Pacific at San Jose, Cal., will hereafter prohibit the entrance of any student who indulges in tobacco in any form.

After an inspection, the proper authorities have declared that the condition of the Almshouse buildings is perfectly safe and tenable.

M. Theodore Weicker, hitherto business manager for E. Merck, manufacturing chemist of New York, has now become a member of the firm.

Correction.—In the last issue of The Times and Register the dose of ergot in the reported case of obstinate epistaxis, page 466, was, of course, ʒjss instead of ℥jss, as an error in the types made it.

Dr. T. G. Pagenheimer has resigned his position as Resident Physician of the Jewish Hospital, and Dr. W. B. Teller has been elected in his place.

It is proposed to move the headquarters of the Hay Fever Association from Bethlehem, N. H., because of the treatment of the citizens of the place.

Dr. Joseph K. Young has been elected Assistant Demonstrator of Surgery and Instructor in Orthopædic Surgery at the University of Pennsylvania.

We are glad to hear that the Columbus *Medical Journal* will not disappear from our exchange table. It is being reorganized, and will be placed on a firm footing.

The new ambulance house and stables at the Presbyterian Hospital has been completed and is now occupied. It is said to be perfect in its fittings and arrangements.

The principal medical periodicals of the world are about two hundred and sixty-six in number, of which 174 are published in the United States, and ninety-two in all other countries.

The *Quarterly Compendium* has gone to that bourne whence no journal ever returns. Its gentlemanly and talented editor will devote his entire attention to the *Medical and Surgical Reporter.*

The Emperor of Austria is establishing sterilizing apparatus on a large scale for the gratuitous preparation of milk for the children of the poor.

—*Jour. of Amer. Med. Association.*

Mrs. Rachel Lloyd. Ph.D., formerly of this city, now Professor of Analytical Chemistry in the University of Nebraska, has been elected a Fellow of the American Association for the Advancement of Science.

The student's numbers of the *Lancet* and *British Medical Journal* are enormous in size for weekly periodicals, and are full of valuable and instructive information about the English colleges and medical courses.

Another martyr to duty was Mr. Charles Brown, M.R.C.S. and L.R.C.P., Lond., one of the surgeons of St. Thomas Hospital, who contracted diphtheria and died of it while assisting in the operation of tracheotomy.

In a Vienna clinic sozoidol-potash was employed as a permanent dressing in a case of amputation of a leg. The dressing remained in place sixteen days, and on removal disclosed a healed surface.

—*Notes on New Remedies.*

The following changes have recently been made in the Faculty of the University of Pennsylvania: Dr. Barton C. Hirst will occupy the Chair of Obstetrics alone. Dr. De Forest Willard will be Professor of Orthopædic Surgery. Dr. Tyson, having succeeded to the Chair formerly held by Dr. Osler, who has gone to Johns Hopkins, will in turn be followed by Dr. Guiteras as Professor of Pathology and Morbid Anatomy.

THE death of a child is reported from the use of chewing-gum. A number of small, round particles of the gum so hard as to cause perforation of the bowels in several places was found at the post mortem.

MR. GOSCHEN, the British chancellor of the exchequer, said in his last budget that in his opinion the increased toying with the cigarette after dinner was partially accountable for the decreased consumption of wine. Men smoked more and drank less.

DR. DAVID S. GLONINGER, a well-known obstetrician of this city, has just died. The doctor was sixty-one years of age, was a son of Dr. John W. Gloninger, of Lebanon County, and was a graduate of the University of Pennsylvania. He leaves among other children a son, who is also a physician.

THE DECREASE OF HOMŒOPATHY IN EUROPE.—In Austria there are only 218 homœopathists, out of the whole number of medical men, which is 7183; and only 44 of these profess to practise homœopathy exclusively — and the number also is said to be steadily decreasing.

DR. T. LAUDER BRUNTON says, in the *Lancet*, that sulphonal appears to be one of the most effective of all the newly introduced hypnotics, and although it does not, like morphine, compel sleep, it induces sleep in a pleasant manner, and has few disagreeble effects and little or no danger.

THE following subjects are announced for the meeting of the Fifth International Congress of Otology, to be held in Florence in 1892: 1. The Pathological Anatomy of Inflammation of the Middle Ear. 2. The Diagnosis of Cerebral Abscess caused by Ear Disease. 3. General Therapeutics of Ear Diseases.

A NEW SWISS PHARMACOPŒIA is shortly to be published. A request has been sent, by the collaborators, to Swiss medical societies and practitioners, requesting suggestions as to the introduction of new remedies and the retention of old ones.

—*Jour. of Amer. Med. Association.*

DR. BRIAND, a young French physician attached to the hospital at Villejufi, attempted to cure consumption by gradual exposure to cold air. It is said the results were such that several of the patients on whom the "elixir" treatment was tried now sleep on the open ground in all weathers, and with never a complaint.

A LAY contemporary has learned "what killed Maybrick," and answers the question by copying from "an English medical journal" the list of the drugs which were administered to Mr. Maybrick during his illness. This list is as follows:

Morphia suppositories; ipecacuanha wine; papain and iridin solution; cascara sagrada; nitro-hydrochloric acid; tincture of nux vomica; Fowler's solution; Plummer's pill; dilute hydrocyanic acid; tincture of henbane; bromide of potassium; antipyrin; tincture of jaborandi; bismuth; cocaine; nitroglycerin; dilute phosphoric acid; solution of chlorine, Sanitas, glycerin and Condy's fluid, as mouth washes.

—Boston *Med. and Surg. Jour.*

DR. SUDDUTH is showing the dentists the value of a journal which is free from the trammels of business interests. The appearance of the *International Dental Journal*, published by a dentist and backed by an association of leading dentists, was sure to be followed by the fall of the trade journals from the position they had previously occupied.

MENTHOL, according to the *Prager Med. Wochenschr.*, acts as a good anodyne, and is valuable in the local treatment of laryngeal tuberculosis. A ten per cent. solution should be used in the beginning, to be gradually increased in strength; a forty to fifty per cent. solution, however, causes severe irritation.

Notes on New Remedies.

DR. WILLIAM F. WAUGH has just been elected a member of the Continental Anglo-American Medical Society, which will meet in Paris, September 30, 1889. The following are the honorary presidents of the Society, one of whom will occupy the chair: Sir Spencer Wells, Sir Joseph Lister, Prof. Ball, Prof. Brown-Séquard, Drs. Richard Quain, Ricord, J. S. Billings, Fordyce Barker, and Weir Mitchell.

HOW BEEF EXTRACT IS MADE.—A man at Colchester this week has been fined forty shillings for driving a dying horse with cruelty. He was taken into port for transhipment to Antwerp, where it seems they boil down old screws and send the results back to English invalids for beef tea. The newspapers have fully explained the process, and now compressed beef, extract of beef, and beef tea with an Antwerp brand are a drug in the market.—*Press.*

DR. ADDINELL HEWSON died at his residence, 1434 Spruce Street.

Dr. Hewson was born in this city on November 22, 1828, his parents being Dr. Thomas T. and Emily (Banks) Hewson, making the fourth generation of physicians in the family. Dr. Hewson received his preliminary education at the University of Pennsylvania, both in the academic and art departments, and his early professional education at the Jefferson Medical College, from which he graduated in 1850.

He subsequently pursued his medical studies in Dublin and Paris. While in Dublin he was notified of his election as Resident Physician at the Pennsylvania Hospital, and returned to this city to assume the duties of that position. Since that time he has been a resident of this city, making a specialty of surgery.

Dr. Hewson was well known both as an author and an editor. In the latter capacity, he, in 1853, edited Wilde's "Aural Surgery," at the request of the author. He was also editor of the American edition of Mackenzie's "Diseases of the Eye." Among his own works was "The Use of Earth in Surgery," that attracted much attention, as well as a paper on "The Influence of the Weather Over the Results of Surgical Operations."

Dr. Hewson was a member of the State and County Medical Societies, of the College of Physicians, the Pathological Society, the St. George's Society, and the Academy of Natural Sciences.

A Miss Chauncy, of Columbus, Ohio, has had a fright that will doubtless teach her a lesson. She used for her complexion a mixture of arsenic and nitrate of silver. Then she went to the White Sulphur Springs and took the baths. The sulphur decomposed the silver salts in her skin and turned her so black that she has gone into retirement and will not be seen again for a year.—*Times.*

The International Tooth Crown Company has brought a civil suit for $60,000 and six months' imprisonment against Dr. J. W. Crouse, of Chicago, for interfering with their business. The American Dental Association has voted $1000 for Dr. Crouse's defence, and the members added $2000 by private subscription. The dentists seem to be awakening to the necessity of opposing the monopolists.

The late reports in regard to the disastrous financial condition of Johns Hopkins University seem to have been without foundation. President Gilman authorizes the statement that the University will begin its new year on the first of October with unimpaired efficiency. A lectureship in literature has been endowed by a gift of $20,000. By the bequest of John W. McCoy the University inherits 8,000 volumes, and is the residuary legatee of his estate, estimated at above $100,000, exclusive of the library. Within six months $300,000 have been received, and other gifts are expected.

Dr. Thomas S. Reed, of this city, died suddenly from angina pectoris, in his cottage on Lafayette Street, Cape May. His health has been failing for two years, and he has been frequently subject to acute attacks of the ailment which proved fatal. His death was brought on by over-exertion.

Dr. Reed was born in Millville, April 1, 1822, and was a self-made man. At odd hours he spent his time in educating himself. He subsequently taught school for several years, and saved enough money to study medicine, and graduated from the Jefferson Medical College in 1846. When he retired, in 1871, he had the largest practice in Southwark, and was ranked among the foremost of Philadelphia's physicians.

For some time past physicians in Nicetown, Tioga, and the lower end of Germantown have been expressing their belief in the necessity for a new hospital to cover the field between Falls of Schuylkill and the North Pennsylvania Railroad, the lower end of Germantown and Lehigh Avenue, accident and other cases now having to be taken either to the Germantown, Jewish, or Episcopal Hospitals, which are in most instances long distances away.

In order that the matter should take tangible shape sooner, several physicians in the localities named have formed a medical society called the North Philadelphia Medical Club, and have elected Dr. J. K. Cassel, of Nicetown, President, and Dr. W. G. Howell, of Tioga, Secretary and Treasurer.

The Club proposes to establish the hospital and dispensary as soon as it can secure suitable quarters. Negotiations are now in progress for a property in the neighborhood of Germantown Avenue and Butler Street.

Mayor Fitler has appointed Drs. William F. Waugh, H. C. Chapman and R. G. Curtin the Board of Civil Service Examiners. All candidates for positions under the city government which are occupied by physicians, must come before this Board.

A man from Washington was taken with fits on the corner of Thirteenth and Chestnut Streets and conveyed to the Jefferson Hospital, where he caused quite an excitement among the attachees by rushing on them with an open knife. He was finally restrained and sent to the almshouse. He is considered to be insane.

A Remedy for Insomnia.—A writer in the St. Louis *Globe-Democrat* says: "The abuse of the eye is the crime of the age. I am prepared to demonstrate that at least nine-tenths of the prevailing sleeplessness of which we hear so much is due to nervousness directly traceable to the optic nerve. We are wearing our eyes out over books and desks and types, and the effect shows itself not only in the appearance of the organ itself, but in its retrospective effect on nerve and brain. I have discovered a remedy for sleeplessness, and for the reason I have never known it to fail, I am fortified in my opinion that the whole trouble arises from the overstrain of the eyes. Take a soft cloth—say a piece of napped towel—and fold in it two small pieces of ice at a distance apart to exactly cover the eyes when the cloth is laid across them. Then lie down, adjust the cloth with the ice over the closed eyes, and you will be asleep in a very short while.

To Contributors and Correspondents.

All articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from September 10, 1889, to September 16, 1889.

Walter, Freeman V., First Lieutenant and Assistant-Surgeon. The leave of absence granted on surgeon's certificate of disability, by direction of the Acting Secretary of War, in S. O. 92, April 20, 1889, from this office, is extended one month. S. O. 211, A. G. O., September 11, 1889.

Walker, Freeman V., First Lieutenant and Assistant-Surgeon. Is relieved from duty in the Department of Texas, by direction of the Acting Secretary of War, and will, upon the expiration of his present leave of absence, report in person to the commanding officer Jackson Barracks, La., for duty at that station and by letter to the commanding general Division of the Atlantic. Par. 2, S. O. 212, A. G. O., September 22, 1889.

Medical Index.

We purpose on this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Case of rupture of the uterus and a case of Cæsarean section, illustrated, William T. Lusk, M.D. N. Y. Medical Journal, September 14, 1889.

Catha eduls, La Egasse. Bulletin Général de Thérapeutique, 30 Aout, 1889.

Contribution to the study of measles, J. D. Smith, M.D., and W. C. Dabney, M.D. Archives of Pediatrics, August, 1889.

Congenital malformations and contractions of the hand and fingers, arising from various causes, illustrated, William A. Elliot. Dublin Journal, September, 1889.

Cholecystotomy, Neil Macphatter, M.D. New York Medical Record, September 14, 1889.

Climate of southern Alberta and its relation to health and disease, G. A. Kennedy, M.D. Journal of Amer. Med. Asso., September 14, 1889.

Climatic treatment of bronchial asthma, the, Knight. *Ibid.*

Cyst of the pharyngeal bursa, Wright. *Ibid.*

Die Lehre vom Stogwechsel und von der Ernärung und die hygienische Behandlung der Kranken, Sée. Deutsche Medizinal-Zeitung, September 5, 1889.

Die Therapie der Acne disseminata, Heitzmann. Medicinische Monatsschrift, September, 1889.

Das phenacetin, Cattani. *Ibid.*

Die akute gut artige Milzschwellung, Tichtner. *Ibid.*

Du traitement de la coxo-tuberculose par l'extension continue, Conners. Annales d'Orthopèdiè et de Chirurgie Pratiques, Sept. 1889.

Ein fall von Diabetes insipidus, Westphal. Berliner klinische Wochenschrift, Sept. 2, 1889.

Empyema, Conkey. Northwestern Lancet, Sept. 1, 1889.

Hémorragie post partum secondaire Traitement de le, par le raclage et l'écou villonage de l'utérus, Misrachi. Bulletin Général de Thérapeutique, 30 Aout, 1889.

Intestinal diseases of children during hot weather, Peter Hooper, M.D. Archives of Pediatrics, August, 1889.

Ist die Knochentuberkulose angeerbt, Dollinger. Centralblatt für Chirurgie, August 31, 1889.

Institutions for the treatment of pulmonary consumption in the United States, Kretzschmar. Med. News, September 7, 1889.

Lenticular regular astigmatism, Swan M. Burnett, M.D. Medical News, September 4. 1889.

Lupus of the throat and nose, Hunt. The Journal of Laryngology and R inology.

Mineral springs of Colorado, Chas. Denison, M.D. Medical News, September 4, 1889.

Massachusetts lunacy law, T. W. Fisher, M.D. Journal of Amer. Med. Asso., Sept. 14, 1889.

Notes on éxalgine, Frederick Peterson, M.D. New York Medical Record, September 14, 1889.

On child mortality and the influence of age distribution as affecting the death rate in Dublin, Sir Chas. A. Cameron. Dublin Journal, September, 1889.

Orthopedic surgery, Moore. Northwestern Lancet, Sept. 1, 1889.

Origin of pus, Wm. Atkinson, M.D., of N. Y. Journal of Amer. Med. Asso., Sept. 14, 1889.

Pathology and treatment of chronic sciatica, J. G. Carpenter, M.D. Journal of Amer. Med. Asso., Sept. 14, 1889.

Partial tenotomies in cases of neurasthenia, with insufficiencies of the ocular muscles, Myles Standish, M.D. Boston Med. and Surg. Journal, September 12, 1889.

Papillomes des Fosses Nasales, contribution à l'étude des, Lacoarret. Re ue de Laryngologie d'Otologie et de Phinologie, September 1, 1889.

Pelvic abscess, Root. Toledo Med. and Surg. Reporter, Sep'ember, 1889.

Pits and Fissures of the enamel, Andrews. The International Dental Journal, September, 1889.

Recent advancement in the treatment of diseases of the skin, Bulkley. Jour. Amer. Med. Ass'n, Sept. 7, 1889.

Recurring œdema of the left upper eyelid, a case of, dependent upon uterine disease (neurotic œdema), Woods. Maryland Med. Jour., Aug. 31, 1889.

Reflex neurosis in puerperal insanity, Macnamara. Northwestern Lancet, Sept. 1, 1889.

Researches in the chemistry of selenic acid and other selenium compounds, Sir Chas. A. Cameron (concluded). Dublin Journal, September, 1889.

Salol in the gastro-intestinal derangements of children, Carr. Archives of Pediatrics, September, 1889.

Short notes on the surgical diseases of children, Edward Borck, M.D. Archives of Pediatrics, August, 1889.

Structure du foie, les conception modern sur la, Pillist. La Tribune Médicale, 29 Aout, 1889.

Simple tests of the ocular muscles, Randall. Medical News, Sept. 7, 1889.

Trichomycosis nodosa, a note on its characters and relation to other hair diseases, illustrated, R. Glasgow Patterson, M.D. Dublin Journal, September, 1889.

Typhoid fever, treatment of, Ward. Kansas Med. Journal, September, 1889.

The University of Maryland from 1837 to 1837; the rupture; the two Faculties; the suit and the restoration of the regents, Cordell. Maryland Med. Journal, August 31, 1889.

Ueber Blasenentzündung nach Tripper, Englisch. Internationale klinische Rundschau, Sept. 1, 1889.

das Maas der Entbehrlichkeit und der Wiederersatz fähigkeit des Leberorgans, Ponfick. Centralblatt für die medicinischen Wissenschaften, August 31, 1889.

die neueren Radicaloperationen an Hernien, Bàron. Wiener Medizinische Presse, August 11, 1889.

die recidivirende Oculomotoriuslähmung, Manz. Berliner klinische Wochenschrift, Aagust, 1889.

Lupus excision und deren plastische Dickung nebst einigen Bemerkungen zur thiersch' schen Transplantation, Senger. *Ibid.*

dos Saccharin aurun, Petschek und Th. J. Zerner. *Ibid.*

das Verhalten der Krankheitseneger der Cholera des Unterleibstyphus und der Tuberkulose in Milch Butter Molken und Käse, L. Heim, Würzburg. *Ibid.*

die elektrolytische Behandlung des chronischen Rachenkatarrhs, Kafemann. Deutsche Medizinal-Zeitung, September 2, 1889.

die akute Leukamie und Pseudoleukämie, Ebstein. Deutsche Medizinal-Zeitung, September 5, 1889.

die praktische Durchführung der Antisepsis am ange, Odler. Wiener Medizinische Presse Sept. 1, 1889.

dithrolsalicylsaures Natron 11, Lindenborn. Deutsche Medizinal Zeitung, September 5, 1889.

Ulterior results of the study and practice of medicine, some of the, McAully. The Maritime Med. News, Sept., 1889.

Undescended and hypertrophied testicle, Hubbard. Toledo Med. and Surg. Reporter, Sept., 1889.

Weitere Beiträge zur Operation des Leberechinokokkus, Krauser. Berliner klinische Wochenschrift, September 2, 1889.

Zur Trage der Ausspülung der Highmorshöhle, Jelenffy. Berliner klinische Wochenschrift, Sept. 2, 1889.

Lehre von der Creolinintoxication, Posin. *Ibid.*

Therapie der Prostatahyopertrophie und chronischen cystitis, Fehleisen. Berliner klinische Wochenschrift, August 19, 1889.

Trage über die Weil'schc Krankheit, Goldenhorn. *Ibid.*

Casuistik der Luxationen und Fracturer, Gorham. Wiener Medizinische Presse, September 1, 1889.

subkutanen Blutinjektion nach der v. Ziemssen'schen Methode, Westphalen Dorpat. Deutsche Medizinal-Zeitung, September, 1889.

Behandluug der Diphtheritis, Derleth. Medizinische Monatsschrift, September, 1889.

Kenntniss des gelben Fiebers, Stief. *Ibid.*

THE PRINCIPLES THAT SHOULD GUIDE US IN THE RATIONAL TREATMENT OF GONORRHŒA.

(Read before the Mississippi Valley Medical Association, Sept. 11, 1889.)

BY BRANSFORD LEWIS, M.D.,
ST. LOUIS.

IF we were to reckon progress in medicine by stages we could select no more apt a term for designating the present one than that of the stage of bacteriology. Bacteriology has assumed such an important role in all that relates to medicine or surgery that our attention is drawn to it in the consideration of almost every subject in medical or surgical science. And yet, dropping from this lofty plane of thought, which tempts us into the field of glittering generalities, and limiting ourselves to the more practical question at hand let us inquire, what has this all-absorbing and comprehensive study and knowledge of bacteriology done for our assistance in the treatment of gonorrhœa? Has the hope of aborting, of quelling, of exterminating the disease by a treatmnt based one the discovery, study and acquaintance with the life-history of that sturdy villain, the gonococcus, been realized? Have the methods of treatment thus brought into vogue accomplished the great wonders expected of them? Have they accomplished anything more than the palliation, to a considerable extent, of the severity of the disease, of shortening, somewhat, the duration of its several stages and of doing away with the old and barbarous forms of astringent, caustic and stimulating injections? I believe that all those who have tried this or that new antiseptic, this or that infallible germicide—not simply on two or three isolated cases in which beautiful results may have been attained and which, by the way, were in all probability not gonorrhœa, I say that all those who have tried such new antiseptic plans of treatment in a considerable number of cases are doubtless convinced that none are infallible; that all are subject to the various influences, deleterious or favorable, that were met with in treating after the older, prudent methods.

Many beautiful and touching theories have been constructed to explain how the gonococcus would quail with fear when, in his revels, he should detect from afar the fumes of death-dealing iodoform brought into action by means of this or that preparation; or of how he would shrink with horror at the prospect of being literally boiled alive by hot injections, or washed out into the cold, cold world by the relentless flood of prolonged irrigation; or of being crushed in spirit, body and soul, by the continuous presence of a medicated gelatine bougie; or dried up into an Egyptian mummy of a coccus in the arid soil of a mildly astringent, antiseptic, non-irritating, magic-healing absorbent powder! But experience with these agents would seem to indicate that the usual rule of the breeding of contempt by familiarity is not broken in this instance. Nay, more! That the festive gonococcus after a time appears to become sufficiently acclimated to enjoy his surroundings, for a while, at least.

And this, notwithstanding the fact that antiseptics do kill gonococci, and with great certainty and facility—when they are in culture fluids. But why not

when they are in the urethra as well? For this reason: The gonococcus in preparing himself for the conflict does not foolishly remain where his foes can get at him with these various medicaments; he makes his landing and starts immediately for the woods, so to speak. He pushes on, by proliferation, between the epithelial cells, breaking through their connecting substance and finally ensconces himself below its deepest layers, along on the basement membrane, and even sometimes within and between the interlacing fibers of this structure. Here he proliferates and disseminates to his heart's content.

This has all been repeatedly and absolutely proved by eminent investigators; Bumm has watched the invasion of the conjunctival tissues by the hordes of gonococci, has seen them penetrate to the connective-tissue layer, and has noted the strong obstruction offered by this tissue to their further progress. Not only this, but he has seen that the effects of astringents applied over the epithelial surface serve only to constringe and harden this covering, which then, indeed, forms a secure protection against the absorption or leaking through of any germicide or antiseptic which, embodied in the injection or what not, has been applied to the mucous surface. Moreover, he has seen that the elimination of the cocci contained in this meshwork of cells and fibers is brought about, not by the penetration of the germicides into the tissues, there to attack the organisms in their strongholds, as has been thought by some, but it is accomplished by a process of proliferation of the connective tissue fibers into which gonococci are unable to penetrate, as intimated above. In the stage of improvement these fibers, incited by the irritation present, increase in number, push forward, driving before them the microbes towards the surface of the membrane, from which they are washed by the outgoing urine or killed by the germicides. When a sufficiently strong connective-tissue bulwark has been constructed, new epithelial cells begin to dot the denuded surface here and there. The cocci have by this time lost much of their vitality and are unable to break them down with the ease shown at the first onslaught. The conditions for resisting their inroads, too, are then more perfect. They lie simply along the surface or amongst the superficial cells.

So that the final process of cure depends not altogether on the extermination of the few remaining gonococci, but also, and perhaps even more especially, on the closing of the tissues against their further invasion by the development of firm layers of this protecting barrier. And the inflammation then persisting may be interpreted as denoting the chronic irritation remaining after the severe disorganization wrought by the previous disease.

It is for these various reasons, then, that in the earlier stages when the gonococci themselves are doing the damage, the efficacy of antiseptics, germicides, astringents, etc., is limited to the position which they now occupy.

In order to overcome these impediments and give access of the medicines to the ambushed cocci, an enthusiastic Frenchman has recently suggested that the epitheliel coat of the mucous membrane be scraped off by a brush-swab, on the plan commonly used in cleaning a pistol barrel; after which the urethra is to be douched with a powerful antiseptic solution. This method is original and ought to prove effective—in producing a stricture, if nothing else. It is certainly more energetic than any I should care to undertake.

I would, therefore, submit that efforts at aborting or killing a gonorrhœa with strong medicines, antiseptic or otherwise, not only do not attain the desired end, but are ill-advised and liable to be followed by unfortunate sequelæ or complications. Consequently, treatment should be based on a plan having for its object the idea of carrying the disease through its various stages, as authors used to say, *tuto, cito et jucunde;* allowing the patient to experience as little discomfort, pain and annoyance as possible, mollifying the inflammatory reaction and destroying, devitalizing and discouraging the gonococci as much as our rather restricted powers will admit of, and hastening the healing process with all possible speed.

To accomplish these ends, having used various forms and modes of treatment, I have concluded that the one offering, with the general run of cases, the most advantages with the fewest objections, is that of giving, in the first stage of the affection, simply alkaline diluents and sedatives internally, making use of such adjuvants as dipping the penis in hot water, etc., and in the second and third stages, giving injections of lanolin, medicated with an absolutely unirritating antiseptic, to which may be added, in the third stage, a mildly astringent and stimulating antiseptic.

As a means of introducing the ointment, I have been using, during the last six or seven months, this hard-rubber applicator, which I present for your inspection. As you see, it consists of a catheter-like stem, perforated at its end, which is inserted into the urethra to the desired depth; a box to contain the ointment, and a piston which is screwed into the box, driving the ointment before it into the stem, and thence, through the perforations, into the urethra. When properly performed, an injection given with this instrument causes absolutely no pain or discomfort for the patient. But sometimes a sudden movement on his part will jog the stem against some tender spot and evoke an immediate and earnest protest. To obviate this, and to leave nothing undone that could in any way assist in avoiding irritation of any kind, I have had some vulcanized soft-rubber stems constructed, which answer the purpose very well. The square shape of the second (modified) box is of advantage in affording a securer hold on it. The stem need not be inserted as deep as its length will permit; the flexibility of the lanolin and elasticity of the urethral walls assure the spreading of the ointment over the inflamed surface.

Messrs. Aloe & Co., of St. Louis, have kindly constructed the instruments for me.

As to my reasons for preferring lanolin to other vehicles, I would say that, with reference to the other vehicles, water, the most common, is itself, in its purest state, irritating, and unless it contain some local anæsthetic, will cause pain; powders or

tablets, though dry and absorbent when first deposited, soon become moist and cake up, losing the properties for which they were chosen. Gelatine bougies give pain at every movement of the body until they are liquefied; mucilages or emulsions present no advantages which are not possessed to a greater degree by lanolin, and—a point of great importance—all of them are lacking in "staying" qualities; with the first passage of urine, out they go, and, in order to make their effect continuous, they must be renewed several times a day, entailing frequent repetition of the trouble, pain, etc., experienced each time.

Lanolin presents none of these disadvantages; it is wholly unirritating—is even soothing to inflamed tissues. When introduced pure, even without any pacifying sedatives, it invariably causes a feeling of relief and comfort to the patient who has been constantly reminded of his ailment by the teasing, harrassing sensation incident to all cases of gonorrhœa. As one patient remarked, the ease afforded allowed him to forget all about it for hours at a time, whereas, before he began to receive the treatment, it was never out of his mind while he was awake. I believe that the principal reason for this is that it keeps the inflamed surfaces apart, preventing their continuous friction and auto-irritation. Actual pain in the urethra is also mollified by it.

The oiliness of lanolin assures its adhesion to the canal walls, even in spite of the flushing of the urethra by the stream of urine. It may be noticed floating on the urine of the second or third passage after the application. It is evident that in this respect, too, it surpasses all of the excipients named. An authority tells us that lanolin possesses antiseptic properties of no mean order.

I shall not take up more time in detailing its many advantages, which are almost self-evident.

As to the medicament employed, any remedy given in solution may be prescribed with equal propriety in lanolin. Of the various drugs which I have used, I sum up my impressions as follows: Bichloride of mercury, even in minute quantities, is too painful or irritating, and frequently causes an increase in the pus formation; carbolic acid is also irritating, but not painful; iodoform might be used were it less perniciously active in its odoriferousness. The zinc preparations are applicable to the later stages, in which they give material assistance towards shortening the wind-up. Resorcin would be a most admirable remedy were it not a most aggravatingly unstable drug. If administered after it has degenerated, it will not be long ere the operator has cause to regret his efforts in the way of economy. Boric acid directly following the increasing stage of the affection seems to fulfil every indication; it is an antiseptic, a germicide, and yet has absolutely no irritating effect on the inflamed membrane. It is capable of killing the gonococci that it reaches, and of preventing attacks from other microbes which give rise to the secondary, or mixed, infection of Bumm. And, by the way, the continuous presence of medicated lanolin forms a vigilant guard against this complication.

Agreeing, then, with the dictum of all authorities of the present day, that gonorrhœa is a specific disease, which cannot be aborted after it is once fairly started, I conclude that:

1. Our treatment should not have for its object the futile idea of jugulating the disease in its early, but established, stages.

2. The endeavor to control its severity, to lighten in every possible way all of its disagreeable features, to shorten its course, and to ward off complications, should be our guiding principles.

3. No local agent does its share in fufilling these indications more perfectly than does lanolin, medicated after the manner suggested.

1006 Olive Street.

MAN AND HIS DEVELOPMENT.

Annual address delivered before the Twentieth Session of the Virginia Medical Association,

By DR. THOMAS J. MOORE,
RICHMOND, VA.

Mr. President and Gentlemen of the Medical Society of Virginia, Ladies and Gentlemen:

IT is with feelings of infinite pleasure that I have the honor of appearing before you to-night in compliance with an established custom of this Society. Permit me, ladies and gentlemen of the City of Roanoke, to express the gratification of the members of this society at the kind and hospitable manner in which they have been received by you. Virginia, always distinguished for her hospitality, has had but a reflex of this noble and exalted quality once more displayed by the inhabitants of this beautiful and romantically located city, lying embosomed in the blue hills of the Appalachians, surrounded by landscapes the most varied and pleasing to the eye, with a climate whose health-giving powers has made Roanoke known beyond the confines of the state; with a population alike distinguished for industry, culture and refinement; with a growth and progress exceeding the expectation of the most enthusiastic of her denizens. Truly, it is a privilege for this society to meet in your midst!

In commencing my discourse, fellow members of the Society, I trust that I may be pardoned for having selected a subject not strictly Medical, as heretofore has been in vogue in this Society. Knowing that my audience would be composed of persons from the various walks of life, I concluded that it would be more entertaining to discuss some question that might prove of common interest to the public as well as to the Profession. I, therefore, have the honor of inviting your attention to Man and His Development. The origin of man as to time is wrapped in the obscurity of the far-distant past. For many centuries after the introduction and acceptance of Christianity, the succinct account contained in the Pentateuch was considered as not only absolute, but decisive upon the subject. This condition of the public mind continued until the commencement of the sixteenth century. The acceptance of the teachings of Copernicus, their enlargement and systemization by Galileo in their relation to astronomy, in the early part of the seventeenth century, had arrested the attention of the scientific and learned and caused no

small degree of skepticism to arise in their minds concerning the accuracy of the account of creation as given by Moses. The science of geology, springing up almost contemporaneously with the science of astronomy, likewise contributed largely to bring about the same result. Leonardo da Vinci and Fracastoro in 1519 discussed the character of the fossil remains found imbosomed in the earth and reached the conclusion that many of them had lain entombed through countless ages. Numerous contributions were made by geologists during the seventeenth and eighteenth centuries. It remained for Hugh Miller and Sir Charles Lyell in the nineteenth century to show through their works the antiquity of the earth and the character of its formation.

The naturalists in the meantime had not been idle, and in the department of zoölogy Linnæus, Cuvier and Agassiz had advanced their theories in regard to the origin and history of man. At last came Professor Charles Darwin with his great works upon the "Origin of Species and the Descent of Man." The doctrines and teachings contained therein startled the scientific, alarmed the orthodox and attracted the attention of the reading public at large. He declared that all animated nature could be ultimately traced to its primitive protoplasmic essence, and that all animated nature had passed through transitional gradations until it reached its ultimate characteristics and outlined forms through the law of evolution by means of natural selection or the survival of the fittest. The character of this address will not permit a detailed investigation of his doctrines and teachings. The acceptance of his views carries with it no ultimate satisfaction as to the origin of life, for in his attempts to destroy accepted opinions in regard to the divinity of creation, he offers nothing definite and convincing in their stead. That mere physical force and chemical happenings could produce the universe lies beyond the pale of the possible. There must be a great First Cause—the embodiment of all knowledge and power, the essence of all goodness and truth. "The earth is His handiwork and the fullness thereof."

Without further discussion as to the origin of man let us be content to find him where tradition has placed him, in the interior of Asia and near the banks of the Euphrates. From this point he made his departure and in progress of time peopled the earth.

The division of humanity into five grand families or races is now universally recognized; difference in color, physical development, mental character and language are the determining factors involved in these distinctions. That these types were at once developed no one at the present day believes—it was only through the long lapse of time that these changes were accomplished—climate, soil, temperature, physical surroundings and change of social status arising therefrom, brought all of this about.

The social condition determines the mental characteristics of peoples, races and nations. The development of the brain, its size and shape, are direct results; cranial outlines are determined, paradoxical as it may seem, by brain development. Racial characteristics were early apparent. Four types that we recognize to-day stood accurately portrayed six thousand years ago upon the monuments of Egypt, those wonderful structures of art designed for the purpose of perpetuating the great achievements of her rulers, and chronicling the important events that transpired in their respective reigns. The Aryan, the Semite, the Mongol and the Negro are all to be found delineated with an accuracy that the most casual observer could not fail tc recognize. The wooly hair, the black skin, the thick lips, the cranial and facial peculiarities of the last mentioned race, all stand forth in bold relief. Slaves were they even then, and the cord, the emblem of their degradation, was carefully placed around their necks; the lash in the hands of the master, in the attitude of application, was not neglected in order to complete the picture of their helpless and degraded condition. Truly, the sons of Ham were early subjected to the curse that had been pronounced against them. Thanks to the investigations of Champollion, Smith of England, Bunsen and other investigators, we are at last able to determine much of the history, character and peculiarities of these Egyptians; little did they imagine that in chronicling the events of their dayand generation, in this crude and fragmentary manner, they were to become the sole determiners of the history of the past. They played no mean part in the great drama of life; what they have left behind, shows them to have accomplished much in the science of government, in mechanics and the arts. They presented the most advanced civilization of this time, they invented many appliances that have come down to us and are in daily use. They offered a home to the Israelite when he was in dire distress and though in the end they oppressed and unmercifully persecuted him, they adopted and educated their great leader and law-giver and were indirectly the means of preserving the nation that gave us our religion and our laws. While at the zenith of their national glory, they were the repositories of all the learning and culture of the globe; to them the Greeks early repaired to be instructed by their philosophers and teachers, and from them they obtained those germs of knowledge which they afterwards turned to so good an account for the progress and development of their own learning and culture.

The race that is of most interest to Europe and America is the Aryan or Indo-European. It peopled the whole of Europe, with the exception of the eastern part of Russia, and from it the white settlers in America are descended. The origin of these people belongs to the far distant past—long before events commenced to be recorded, even tradition the most remote fails to involve them in its maze. They took their departure from the northern confines of India and went forth in two directions; the one to the southeast, traversing and peopling Hindoostan; the other to the northwest, peopling a portion of Western Asia, penetrating Eastern Europe, and continuing their migration until their progress was arrested, upon the one hand, by the confines of the Atlantic, and, on the other, by the surging billows of the Baltic.

Their westward march was both fitful and irregular

--nothing impelled them to move forward save the impending necessity of procuring immediate sustenance. They were barbarians of the rudest character; so primitive were they that the necessity of tribal relations had not been recognized; they were gregarious, it is true, but only in its most restricted sense. The aggregation of a few males and females for the purpose of self-defence was the extent of their social ties. They feared the wild beasts that roamed the forests as much, if not more, than these animals feared them.

The bow and flinted arrow, with a few stone implements of the ruder sort, were their only means of defence. They sought the caverns of the earth and other secure hiding places for nocturnal protection, and failing to find these, like other anthropomorpha, they took refuge in the tallest trees of the primeval forest. To describe how helpless, ignorant, and depraved they were would too far tax your credulity, but I will hazard the suggestion that when driven to dire necessity, they occasionally regarded their neighbors as indispensable to their commissariat, and became veritable cannibals. The climate they encountered was of the most rigorous nature—fogs, chilling blasts, and a penetrating dampness were its characteristics. The fauna and flora were of the most primitive types. The musk ox, the rein-deer, the cave bear, the hairy elephant and the wooly rhinoceros, were their contemporaries. In size, statue, and complexion they resembled more the Laplander or Esquimaux than their present descendants. They fought, they struggled during the long years of this frigid period, through what is now known as the rough stone age, until by and by there came the presage of a better dawning.

The icebergs began to melt, their latent heat was given out, humidity and rigidity of climate were lessened, the sunlight with its general rays caused vegetation in increased and more varied forms to spring up. The larger and more ferocious animals disappeared, and the attestation of their existence is to be found only in the entombed fossils of the quarternary period. The smaller and more useful animals, those in fact that were in future to be domesticated had by this time made their appearance. The habits of man now became somewhat changed; he no longer remained a hunter and rude fisher; he turned his attention in a limited degree to agriculture, and by these various changes, both natural and artificial, he progressed apace; his conceptions of his social requirements, and his social relations broadened; he no longer remained content with his rude stone instruments, but he improved their shape, increased their number, and, when necessary, he polished them. Moving still onward through cerebral evolvement and the teachings of the experiences of the past, man had formed tribal relations on an enlarged scale; he had become to a limited extent a navigator; he had discovered two of the valuable metals, he had learned to melt them in a primitive way, and, by their union, to form implements that were more compact and resisting than any before possessed, and this was the commencement of the age of bronze.

As he had been a cave dweller in the past, from similar considerations, in many parts of Europe, he now became a lake dweller. His new instruments enabled him to cut and saw the logs necessary for pile driving; with these he made his foundations, and upon them he constructed his rude habitation—furnishing alike a home as well as an asylum, when danger was apprehended either from man or beast. To meet the Providential ends of his requirements and to obtain the measure of happiness of which he is capable, man has been endowed by nature with a certain degree of restlessness that impels him forward, be his resistance ever so great. In this way, through the discovery of iron and its application to the useful arts, he had advanced his civilization to such a degree of elevation as to demand the recording of the principal events in his life. This may be considered as the commencement of the historical period, and from this time forward more is to be learned in a century concerning him than in the countless ages of the past. Will any one challenge these assertions that such events have transpired in regard to the man of the past in Europe? While in truth no record appears written upon pyramid, obelisk, or within the tomb; no characters are inscribed upon papyrus or parchment to commemorate these events, yet the hand of nature points with its finger deep down through the layers of silt, sand, and gravel that margin the great rivers of Europe to the human skeletons that lie embedded there, surrounded with the implements they used, and intermixed with the osseous remains of the animals that were their contemporaries in life. The margins, as well as the bottom of lakes in many places, have borne similar attestation of where he lived and of the places that gave him sepulchre.

In the caves of France, Germany, and England are likewise found human and animal skeletons, placed side by side beneath carbonacious incrustations, whose stalactites and stalagmites adorn, grace, and beautify their last resting place.

Like fixed sentinels they stand, placed as it were by nature to guard with sacred care man's last resting place. Yes, here, he has lain through countless centuries of the past, and here he will continue to lie unless disturbed by the hand of man, until the fulfilment of time through the consummation of futurity.

That the various nations which subsequently arose in Europe and certain portions of Asia really sprang from this Indo European race, is amply proved, not only in consequence of resemblance in physical and mental characteristics, but philology has traced through the various ramifications of their present languages the roots that they possess in common, and has been able to reduce all these languages to the primitive original. It would require more time than can be devoted to this branch of my discourse, to attempt to describe how this has been accomplished—suffice it to say, that it is a conclusion that has been reached by all the learned philologists who have during the past forty years investigated this subject.

The progress of civilization in western Asia and all of Europe is marked by epochs of advance and

stasis; the culture and learning of the one has influenced the others, and in ancient time the younger always borrowed from the older. To Egypt the Jew and Greek were alike directly indebted. The former accepted the monotheistic views of the earlier Egyptians, the latter had their polytheistic conceptions confirmed and amplified by those of their own day. What Osiris and Isis were to the Egyptians, Zeus and Pallas were to the Greeks. The Greeks appropriated Isis as one of their divinities and in time gave her to Rome. The great law giver received his education from the learned men of Egypt. The Greeks sought knowledge from her great teachers. The denizens of the valley of the Nile—with her great pyramids attesting the grandeur and the power of the past—had their ambitions stimulated for the preservation and advancement of their civilization in the future. The inscriptions upon her obelisks and her tombs told them of the achievements of her great rulers. The size, extent and architectural display of her temples caused them to regard with awe and reverence the deities which they had been taught, gave to them their wealth and power; the continuance of these depending up their propitiation in the future. The day of their decline came at last—and lower and lower have they descended, until the once proud Copt looks up with pleading supplication to the Nomadic dog he once so much despised. It was to the Greeks that early Europeans looked for learning and culture—they were at this time the only European nation with a history and a literature—experience had painfully taught their prowess in Arms to remote as well as continguous countries. The dwellers upon the Indus, the inhabitants of the Nile and they who hugged the eastern shore of the Mediterranean, had all been made to feel the weight of their hand. In philosophy what masters they gave to us in the speculative field; their maxims are received to this day as the perfection of human wisdom; in the science of polemics none have surpassed them up to the present hour. In tragedy and oratory they are the accepted models of our time. Their statuary have caused them to receive the plaudits of the world—in delicacy of outline and in the faithful portrayal of nature they have never been equalled, and never will be surpassed. Their form of government was not adapted to the requirements of their ruder neighbors—it contained the germs of its own destruction, and in time Greece was forced to succumb to the strong hand of her imperial neighbor.

Rome, appreciating the value of her conquest and recognizing the cultivation and advanced civilization of Greece, was willing to sit at the feet of her wise men and learn lessons of wisdom. She appropriated those things which were useful and best, and in this way preserved them to the world.

Following the Greek, came the Roman civilization. Rome's conquest had not only given her supremacy in Europe, but she is figuratively spoken of as "Mistress of the World." Her subjugations in the west were blessings in disguise for the rude people over whom her eagle soared; were brought in contact with and assimilated many essentials from her civilization. After her acceptance of Christianity in 325, she commenced to exercise an influence in Europe which survived her downfall, and it is felt at the present hour. She taught modern Europe the fundamental principles of legal science, and, to-day, the Teuton and Latin speaking races have accepted and incorporated in their systems of jurisprudence the cardinal features of her civil law. Her literature and her learning have come down to us, and her language is destined to live so long as the Catholic Hierarchy prevails or has a religious element to predominate. We owe her a lasting debt of gratitude for introducing Christianity to the great west; and by her sanction of the church, causing the latter to become active in spreading and teaching the essential principles of the great moral law.

Less than four centuries had passed ere we find that Christianity had traversed the whole of Western Europe. England had received "the glad tidings of great joy" from the eminent, pious and active Augustine (610). It would be a work of supererogation upon my part to endeavor to point out the blessings Christianity has bestowed upon society; her growth and progress are coincident with the march of civilization. The former offered to the world the foundation for the construction of social order, and the establishment of civil government; the latter through the laws of evolution, through the test of experience, and by a proper comprehension of essentials, enlarged the sphere and increased the influence that Christianity has exercised over those nations which have accepted her dogmas and teachings. Hand in hand they have gone together, marching through centuries of time, engaged in the laudable undertaking of improving the social condition of humanity at large. The church became the great preservator of knowledge and learning through the dark ages. From the time that the Barbarians had humbled, humiliated and destroyed Rome (476) to the revival of letters in the fifteenth century, her organizations and institutions alone remained intact, her monasteries and convents became the asylums for the persecuted and friendless. She became the grand repository of the learning of the past, and when society, after passing through a stage of degraded ignorance, had undergone sufficient intellectual reaction to appreciate the learning she held in store, once more she came forward and "lifted out of the slough of despond" the ignorant masses of humanity.

When Gutenburg, in 1423, invented the movable type, a revolution was accomplished as it was in a day. The importance of discoveries either in science or applied mechanics, is rarely appreciated by contemporaneous society; such was not the case in regard to printing; at the termination of the century (1500) two hundred printing presses were at work throughout Europe. The knowledge of the past was eagerly collected, and learning in its multifarious forms was permanently preserved for future instruction. The number of educated men in proportion to the population of the respective countries was, of course, lamentably small; the advantage of printed books was that it enabled the educated of all these countries to have access to the current literature of the time.

Society marched apace, and sections of territory were shaped into nationalities. The distinguishing characteristics of localized people began to manifest themselves. Race prejudice became predominant; isolation was regarded as essential for the preservation of national autonomy.

To this there was one general exception, they were united in convictions upon the subject of religion. This happy condition was not of long duration; the absolutism of Rome made her both dogmatic and exacting, the western world was intolerant of restraint, and her learning had awakened her naturally speculative disposition; she revolted at the idea of absolute dictation, and in many sections certain dogmas of the church met with positive rejection. The reformation came to the relief of the non-canonical, and after more than three centuries of active speculative disquisitions upon the religious questions at issue, after appeals to arms in various directions, the relative right of the exercise of private opinion was finally conceded at the treaty of Westphalia in 1648.

I have not, heretofore, alluded to the influence exercised by the Moors during their seven hundred and eighty years sojourn in Spain. They invaded Europe in the midst of her period of greatest social depression; their ambition was territorial acquisition, they overran the greater part of the Spanish peninsula, they passed the Pyrenees, the immediate goal of their desire being the subjugation of the Franks. Their continued successes created general alarm; army after army had gone down before them. It remained for Charles Martel, near Poitiers, to give them in seven hundred and thirty-two, the coup de grace as to French territory. Had this victory been otherwise, the face of Europe might have been changed, and the prediction of one of the faithful (Muza) "that Mahomet should be proclaimed in the Vatican," would have been literally carried out. The Moor was no barbarian, he had drank deep at the fountain of knowledge; he came to Europe a graceful, learned and accomplished man, he held in great contempt the ignorant and semi-civilized native. He brought with him the concomitants of civilization. The teachings of Aristotle, Grecian literature, the science of Greece and Egypt were introduced by him. He gave them arithmetic, algebra, and the pendulum (for measuring time). He taught them the table of signs, the nature of twilight, the relation of the heavenly bodies and the spheroidity of the earth. He introduced chemistry and the medical works of the Greeks and Arabs, the former at that time unknown in western Europe. His eye for the beautiful was displayed in architecture and landscape gardening. Their mountain homes bear to this day the traces of their former beauty and elegance. The transitions wrought by time, even the defacements of the early Spaniards, have not destroyed the beauty, richness and varied elegance of the Alhambra.

The entrance of the Mussulman into Spain and his aggressions in the east, alarmed the whole of the Christian world and caused the Crusades to be organized in the eleventh, twelfth and thirteenth centuries. These expeditions were undertaken for a double purpose, the political feature being the actuating motive of the Pope and his coadjutors—the masses were enlisted in the cause by an appeal to their fanaticism. Jerusalem and the Holy Land must be rescued from the infidel. History records the deeds of valor and courage displayed by both sides. While the Christian could point with pride to the achievements of Godfrey and Richard, the Mussulman with greater satisfaction could refer to the exploits of Saladin and Kelaun, for, in the end, they prevailed. He who was held in such contempt as being at best but an infidel dog, was found to be a foeman more than worthy of their steel. For he not only succeeded in regaining the region from which he had been driven, but retained in his possession those sacred spots around which, to the Christian, clusters so many hallowed associations.

While the Crusaders were defeated in their objects, their expeditions were to those who survived of incalculable benefit. These unlettered sons of the various nationalities were brought in close relation to the Church, for under her banner they had enlisted; their moral nature was appealed to, the active incentive of their lives was the propagation and maintenance of their creed. In the course of their journey through Southern Europe, they came in contact with the most advanced civilization of the western world. Rome, the Eternal City, with much of the retained splendor and elegance of the past, was to them doubly impressive as being the home of the head of the church. They returned to their native lands with enlarged views and more elevated sentiments. They were prepared to become the leaders in their respective countries of the progressive march of civilization.

The general advancement of Europe became marked after 1648; the absolutism of the church was broken —the exercise of private judgment in religious as in secular matters was, to a certain extent, conceded. Literature and learning had received a great impulse through the invention of printing. Knowledge became more general, and the speculative tendencies of the western mind were more actively brought into play. The possessors of analytical rather than synthetical elements of mind, they were more prone to skepticism than belief. They were desirous of reducing everything to primitives; neither their conceptions nor imaginations were of that nature which would lead to the construction of a creed or creation of a religion. It is to the East that we must look for instruction upon these subjects.

To the far East, away inthe interior of China, there came to the front a teacher and philosopher who had caught the divine spark, yet laid no claim to divinity of person or inspiration as to knowledge. His maxims and his philosophical teachings have been adopted by millions of human beings for more than 2300 years. A century earlier had arisen the great teacher of India; his birth was surrounded by mysteries the most profound, and his disciples deified him; he left behind him a creed and a religion which has proved irresistibly captivating, not only to the people of his native land, but kindred nations arose as one man to accept his dogmas and to worship him.

Examining this question further, we find in the East, amongst the Semitic race, the creation and pro-

pagation of a religion nearly six centuries younger than our own, whose votaries are to be found on the three continents of the eastern hemisphere. The Aryan, the Semite, the Mongol, the Turanian, and the African, all contribute to swell its numbers. Bold and aggressive are and have been its adherents. The people of Europe have more than once been defeated by them on well-contested fields. They drove the Christian out of Palestine, the land he loved so dearly, and they hold it unto this day. They have crossed the Hellespont, subjugated a proud and illustrious Christian people, and retain possession of one of the fairest sections of Southeastern Europe.

Once more we look to the East, and find that a branch of this Semitic race became the custodians of the divine law. More than three thousand years ago, standing at the base of the sacred mountain, Moses delivered to God's chosen people the grand decalogue, the embodiment of all justice and equity, the condensation of the essentials for man's guidance in life.

From these people Christianity sprang. It would be superfluous to attempt to portray the benefits it has conferred upon society.

The acceptance of its doctrines and its teachings determined the social condition of Europe—the rejection upon the part of the East placed that population in a state of stasis for many centuries and finally brought about their gradual decline; far have they descended in the social scale and it is difficult for the casual examiner into the history of Asia and Africa to appreciate the transformation of many of these nations in the past. Of the greatness of their power, the extent of their wealth, the measure of their intelligence and the influence they exercised upon the social condition of the West, one may read but he will fail fully to comprehend. Thus nations and people have gone on acting and reacting, the one upon the other, since society was organized; and thus they will continue to do until the fulfilment of time.

Could we examine this subject more in detail we would then more fully comprehend the relations of nations, the one to the other—to what was attributable their rise, progress and development, and in regard to those less fortunate wherein lay the germs of their decay. Europe and America owe to the East a debt of gratitude that it will be most difficult to pay; but well have they set about their task—the teacher and the missionary they are sending everywhere amongst them. Remarkable is the transition when we find the Gospel carried to the very people where it was originally proclaimed, but rejected by the nations whose civilization and progress have reached the highest degree of elevation through its acceptance.

Would that time permitted the portrayal of man's development through the eighteenth and nineteenth centuries. It would offer us much that would prove both singular and interesting; it would show that while he is apparently a free agent as to thought and personal action his ideas, sentiments and feelings arise from a complexity of causes which constitutes the civilization that surrounds him. Heredity, soil, climate and social conditions past and present are the component elements that evolved him. He is chained to his civilization by links that were forged before his time, he cannot rend them, he must progress in its directing lines. Society made wonderful strides in the last century—her progress has been more rapid in the present. The past fifty years has presented a spectacle that the greatest optimist could not have foretold.

The introduction of steam and of the telegraph marked a new era in our progress. They have annihilated space and brought into close relation the countries of the world. They have broken through barriers, overcome prejudices, and bound together through intellectual ties the learned in every land. The essential fundamentals which constitute the true basis of society are becoming generally and universally appreciated. The tendency is towards the universal establishment of a common brotherhood, based upon an equality arising from oneness of thought, sentiment and idea upon all essential subjects. When this is brought about a common language must follow; a language which, when spoken by the Arab or Hindoo will be fully comprehended by the Chinaman upon the one hand and the European and American upon the other. What strength, what progress may we not then look for! The intellectual improvement of man may then be marked by decades, certainly in each recurring generation. Then will we have a genuine millennium—human happiness will have reached its highest possible earthly attainment and there will be nothing left to look forward to except the transition into the grand, glorious and eternal beyond.

SOME OBSERVATIONS ON THE PROPER FORM OF A BOUGIE.

By MARTIN RIVELY, M.D.,
PHILADELPHIA.

As the result of many conversations with physicians, and of a close observation of the current literature pertaining to the urethra and bladder, I am convinced that very imperfect, and not infrequently very erroneous, ideas are entertained in regard to the true anatomy of these parts. We often see allusions made to the neck of the bladder and its sphincter, when, properly speaking, the bladder has no neck, and the sphincter is something very different from what is usually imagined. As a proper conception of the anatomy is necessary to an understanding of our subject, I will be excused for calling attention to some anatomical facts.

Henle locates the sphincter of the bladder in the prostate, and Budge proved this view correct by experiment. The membranous portion also plays a part as sphincter when the prostatic becomes distended.

Dr. E. Finger, in his article on Blenorrhœa in the second volume of Wood's *Med. and Surg. Monographs*, speaks as follows: "When empty, the bladder, on account of the tonus of the muscular tissue, forms a tensely contracted sphere, whose mucous membrane is everywhere in contact, so that it possesses no lumen, or a very slight one. The bladder hangs upon the pars prostatica as upon a pedicle."

As the bladder begins to fill, the pars prostatica remains closed, the bladder dilates and becomes more and more spherical. "But as the distention of the bladder increases, the pressure exerted by the fluid upon the ostium vesicale also increases, and finally becomes so considerable that it first overcomes the elasticity of the ostium, and then the tonus of the internal prostatic sphincter dilates the latter, and the fluid then begins to enter the posterior part of the pars prostatica. The hitherto sharp boundary between the bladder and urethra is abolished at this moment, the transition becomes a gradual one, and a 'neck of the bladder' is formed." Thus, it will be observed, that the "neck of the bladder" is the prostatic portion of the urethra more or less filled with urine. "The moment of entrance of the first drops of urine into the pars prostatica is also the time at which we feel the first desire to urinate."

Now, upon the preservation of the muscular tone of the internal extremity, or deeper portion, of the urethra depends the preservation of perfect control over the function of urination.

Last winter, a gentleman, aged twenty-two years, applied to me to be treated for stricture. On examination, I found that he had two strictures of large caliber, one at one inch, and the other at three and a half inches from the meatus. He had elsewhere been treated for a supposed stricture in the membranous portion, or at the bulbo-membranous junction. His meatus had been split, and steel bougies as large as No. 38 had been passed through into the bladder, causing him exquisite pain, and usually being followed by quite profuse bleeding. He asked me whether I did not think it injurious to pass large instruments into the bladder, for he had noticed that, since his severe treatment, when he felt a desire to evacuate his bladder the urine would dribble away before he intended—in other words, his sphincter had been deprived of its tone. This is a danger which must be confronted by him who insists upon forcing large instruments into the bladder, notwithstanding the fact that no pathological condition exists lower down than three or four inches. In some of these cases it is not easy to restore the lost tone; in truth, I know of one poor fellow who is likely to go through life with impaired control over his bladder.

Another point to which I would call attention in the anatomy of the urethra is the relative caliber of the different regions.

This subject was much discussed some years ago, when Otis maintained that the meatus should be of the same caliber as the remainder of the canal, and allowed very little for variations in circumference in the different parts of the canal.

It will be remembered that the late Prof. Sands, with many others, both in this country and abroad, confuted these ideas, and proved that the urethra varied considerably in its various portions. It was shown, by casts and measurements, that the meatus and the membranous part possessed the minimum diameters in the large majority of cases. In four casts of the urethra, exhibited by Prof. Sands, the internal meatus is shown to be the narrowest part in the first, with the membranous portion coming next, and the external meatus third; in the second cast the external meatus and the membranous portion are of the same caliber and much smaller than any other part; in the third cast the external meatus is the narrowest, and the membranous part next; and in the fourth cast the external meatus and the membranous part are of the same size and much smaller than any other part.[1]

Bad results sometimes arise, not only from overdistention of the deep urethra, but also from ordinary instrumental manipulations. Otis says that orchitis is recognized as occurring not infrequently from the simple passage of any instrument through the curved portion of the urethra. After operations his plan was never to pass beyond the bulbous urethra if it were possible to avoid it, because in six out of seven cases in which urethral fever followed urethrotomy the operation was in the curved portion, the other one was in a malarial subject. In one of my cases, in which I passed a bougie into the bladder, epididymitis followed, and I am convinced that I do not stand alone with this experience. When we consider the fact that but a small proportion of organic strictures is found below the bulbous portion of the urethra, it would seem strange that the surgeon will persist in exposing his patients to the risks he continually does, were it not the case that the steel bougies ordinarily manufactured need to be passed several inches past the stricture to procure dilatation to the full capacity of the instruments. If we find a stricture four inches from the meatus, which we wish to dilate to thirty, we must, with the ordinary conical-shaped instrument, pass our No. 30 bougie more than three inches past the stricture—right through the prostatic portion—or else pass a No. 37 or 38 through the meatus so as to procure a dilatation of thirty, while at the same time passing the point of the instrument but half an inch through and beyond the stricture.

Now, to obviate this difficulty, I had Mr. Wm. Snowden make me a set of steel bougies which taper for only half an inch, and thus have their full size about half an inch from the extremity. With these I am able to stretch a stricture to the full size of the bougie, while at the same time I need go but half an inch deeper than the stricture; and I find it seldom necessary either to cut a meatus or to enter the prostatic portion of the urethra. It might seem at first thought that these instruments, because of their lack of gradual taper, would be much more difficult to pass than the ordinary conical ones; but this is not so. All they require is a little more patience on the part of the operator for their successful introduction.

2300 GREEN STREET.

DR. FERGUSON, who carved the dead body of young Doty without warrant at the New York Hospital on Sunday, is the same gentleman who is under indictment for a somewhat similar offense in the case of Bishop, the mind reader.—*Times.*

Hydrotherapeutics.

By S. BARUCH M.D.
Attending Physician New York Juvenile Asylum and Manhattan General Hospital.

V.

RATIONALE OF TECHNIQUE IN FEVERS.

IN the last article the method of managing fevers by the bath was described. Typhoid fever being the chief of these, their application to its treatment was dwelt upon in detail.

The rationale of the action of hydriatic measures in fevers may now be profitably considered, inasmuch as this will afford a guide to a correct appreciation of the various methods and a warning with regard to the necessity of strict adherence to their minutiæ.

I reiterate that in no department of therapeutics may so exact and scientific a rationale be worked out. In other branches we find our chief support in purely empirical data, the rationale of action of a large proportion of medicinal agents resting upon conjecture or upon more or less satisfactory deduction from experiments on animals.

How different our position is regarding hydrotherapy, its application in fevers demonstrates conclusively.

Were the only object of fever management the reduction of the elevated temperature, which is indeed the most prominent manifestation, the problem would be simply and empirically solved by the numerous medicinal antipyretics which enable us to reduce temperature ad libitum. But this idea which has held sway over the profession for a considerable time has proven as fallacious as the analogous one that by controlling the circulation and reducing the rapidity of the pulse, by venesection and later by veratrum viride, aconite, etc., febrile diseases might be jugulated. These symptomatic remedies, while affording a certain degree of comfort and in some febrile conditions aiding in the promotion of recovery, if audiciously administered, fail to meet the issues involved in the infectious fevers. In the latter, which form the large preponderance of our clinical work, we have a self limited disease due to a process which cannot be removed by any known method, and only one of whose manifestations is an elevated temperature, while local complications, ulcerations, hypostases, and organic degenerations follow in its train, in proportion to the intensity of the infective process, the type of the disease and the power of resistance existing in the organism attacked. What, then, are the leading indications in the management of such a fever, of which we may take typhoid as an example?

The infective process is beyond the influence of our best directed efforts. While much has been accomplished in the direction of preventing its invasion into the human body, we must acknowledge that once it has forced an entrance, we stand powerless in any attempt to diminish or remove it.

It is the first duty of a general to ascertain as precisely as possible the exact position and strength of his enemy's forces, the next—to prepare to meet him. The infective process is entrenched in the organism and throws out its columns of attack as follows:

1. An elevated temperature deprives the patient of comfort, disturbs his sleep, impairs his functions and, if prolonged without decided remissions, surely leads to serious damage.

2. A reduction of heart power presents even a more formidable menace to the organism than the elevation of temperature. This is due according to Marey and others to a paralysis of the muscular coats of the vessels and consequent loss of tone in their walls, which embarrass the cardiac action, and later to an organic degeneration of the heart muscle which is not the outcome of the elevated temperature as I have elsewhere shown, but of the combined influence of the latter and of the infective process.

3. A failure of the innervation is manifest from the beginning in the malaise, lassitude, ataxia, somnolence, and other adynamic manifestations, and in more intense infection, culminates in stupor, delirium tremor, subsultus, etc. The impairment of the functions of respiration, circulation, nutrition and secretion, over which the nervous system presides, affords striking evidence of the inroads which this portion of the enemy's column is making upon the organism. These, then, are, briefly told, the columns of attack, which we are called upon to antagonize and repel. Their defeat is a question of self-defence, for modern therapeutics no longer pretends to attack the enemy in these cases; we simply fortify the organism and defend it against his onslaughts. That this defensive action is most successfully executed by hydriatic measures, clinical evidence, sustained by large and reliable statistics, has abundantly demonstrated.

1. The reduction of elevated temperature by baths is a strictly scientific proceeding. Rosenthal, Leyden, Botken, and others have clearly demonstrated that in many forms of fever the rise of temperature may be traced to a diminution of heat dissipation from the surface, which results in actual retention and accumulation of heat in the body. These and other investigators have also shown that the evaporation from the surface is inhibited, and, therefore, a retention of water is added to that of heat. Now, *both of these direct factors of temperature elevation are simply and scientifically removed by hydriatic measures.* It is the chief object of the latter to improve the tone of the superficial vessels, to actively dilate them, and thus increase the heat dissipation, as has been again and again demonstrated by Winternitz and others; and also to increase the elimination of water from the surface.

Here we are met at once with the importance of precise attention to the method of bathing. To immerse the patient in a full bath of low temperature, or to wrap him in ice sheets, as has been done in some hospitals, would result in closing the superficial vessels, and keeping them closed. If such treatment does not induce collapse, reaction may slowly take place, and the former high temperature is again reached. If, however, the patient is carefully placed into a bath of 65° to 70° F., and constant and unremitting gentle friction is practised over his entire body, the coats of the superficial vessels are stimu-

lated, reaction form the first shock ensues, the vessels contract rapidly and dilate actively, as the ruddy condition of the skin which has been subjected to friction testifies. This condition is maintained by an occasional basin of cold water poured over the neck and shoulders, followed by friction. The mechanical irritation not only removes the obstacle to heat dissipation but, as Weyrich has proved by exact experiment, it increases the elimination of water from the surface 60 per cent. Moreover, the cooled blood is sent from the dilated vessels back to the interior of the body, and thus a direct cooling effect is produced besides. The baths, therefore, *when combined with friction and douching*, fulfils both indications for removing high temperatures, while medicinal antipyretics fulfil only the first—heat dissipation. The latter, we must confess, is far more effectively accomplished by the medicinal antipyretics than by baths. But while this is true, and while antipyretics are more readily administered and do afford the patient great comfort, they fail to reach the most vital indication in infective fevers, which is the counteraction of the toxic effect upon the innervation, and to which I will return below. Aside from this fact, clinical evidence has accumulated to demonstrate that the action of medicinal antipyretics embarrasses those functions of the body which aid in the elimination of toxic elements.

The recent discussion of this subject, introduced by Dujardin-Beaumetz in the Paris Congress of Therapeutics, but confirms the results of previous investigators.

Lepine found that all those antipyretics which are nervines, exert an inhibiting effect upon the activity of the protoplasm; they destroy chiefly the red corpuscles, either by converting the hæmoglobin or by attacking the cell structure itself; *they act as poisons to the protoplasm* Desplats, though favoring medicinal antipyretics in fever of short duration, decidedly favored Brand's baths in continued fevers, especially with a tendency to adynamia or ataxia. Stokvis thought the antipyretics dangerous, and Semmola agree with him that although the patient experiences a certain degree of quietude, this is obtained at the expense of loss of strength. Indeed, there was almost a consensus of opinion in this direction. While, therefore, we may advantageously resort to medicinal antipyretics in the ephemeral fevers, hydrotherapeutic measures alone will meet the second indication.

2. The enfeebled heart power is the result of loss of tone in the smaller vessels, and later of parenchymatous degeneration due to the infective process plus high temperature. As Winternitz has so ably shown, we have here an imitation of Golz's experiments on frogs, which demonstrated a loss of tone in the vessels of a large area of the circulation and a diminution of the tension in these vessels enfeebles notably the action of the heart. That we possess in the cold bath, combined with friction and gentle affusion, an effective agent for the restoration of the lost tone of the coats of the vessels is proved by the exact experiments of Winternitz, and that this effect, together with the reflex stimulus conveyed to the nerve-centers governing the heart, from the peripheral cutaneous nerve endings, refreshes and invigorates that organ, lessens the number, and increases the force of its contractions, and prevents dicrotism, is positively demonstrated by sphygmographic tracings.

In order that the tonic effect upon the heart be continuous, it is important that the bath be repeated at sufficiently frequent intervals (three hours having been ascertained as the proper average). The effect upon the heart and vessels must be watched.

In the early stages of typhoid fever, when reactive power has not been much enfeebled, chattering of teeth, facial pallor, and a small pulse ensue later than in the more advanced stages. But these should not deter us from continuing the bath; they demand increased friction of the surface, and perhaps a little alcoholic stimulant. If superficial hyperæmia is readily induced by the friction, a small pulse, or even a pinched countenance, does not demand removal from the bath. Only decided chilliness and prolonged chattering of teeth are indications for removing the patient. Sphygmographic tracings have afforded positive evidence of the fact that while the pulse feels small after the bath, it has gained in force and tension, and continues to so gain until the effect of the bath passes away.

In advanced stages, the effect of the cold bath is not so pronounced, because the reactive power is more in abeyance. In these cases, especially when heart failure is threatened, we seek the aid of digitalis, strophanthus, and alcoholics, occasionally with good results, more frequently without benefit. Clinical evidence has proved that by seating the patient in a warm half bath (water covering only a portion of the lower part of the body, and pouring from a pitcher water at 60 to 65° over his head and shoulders, he may often be rescued from a wellnigh hopeless condition. The reflex effect upon the vagus deepens the inspiration, a fresh supply of oxygen is carried to the feebly expanding lung, the heart is aroused, hypostatic embarrassment is overcome. The whole aspect of the case is changed by the brief application of cold to the surface, followed by rapid drying. Now stimulants act more efficiently; their effect is more enduring.

The testimony of that experienced clinician, Winternitz, which has been confirmed repeatedly, should be borne in mind, when the terrible collapse menaces life. "Collapse," says he, "is almost universally regarded as a counterindication to every application of cold. I would again express the opinion, that *I know no more powerful nor effective agent for combating threatening or existing collapse than the intense and intelligently applied excitation by cold.* How often have I seen in advanced fever processes, in degenerated typhoids, a rapidly favorable change wrought in the corpse-like coldness of the extremities in the most serious manifestations of nerve adynamia, in the hypostatic congestion of lungs, by one dipping into a very cold bath, or one cold affusion. I am firmly convinced that very often these manifestations are not due to heart feebleness, but to a collapse of the vessels, and here an *evanescent but energetic* ex-

citation by cold is the only reliable remedy, as I have repeatedly proved."

3. The failure of innervation, referred to above, offers, perhaps, the most serious menace to life, because its deteriorating influence is expended through numerous channels. Hitherto this indication has been met, and to-day is but too frequently met, by alcoholic stimulants and nervines. That these enable us to tide over a dangerous period occasionally admits of no doubt. But here again we have abundant clinical evidence demonstrating that in the cautious and judicious application of cold water we possess a nerve stimulant of vast and manageable power—a stimulant which invigorates the nerve-centers presiding over circulation, respiration, nutrition, and tissue change, and thus enables the system to bear the stress imposed upon it by the infective process under which it is tottering. In these fevers the cardinal point for which we strive by hydriatic measures, is the attainment of an enhanced power of resistance, which, in self-limited diseases, is all that can be accomplished by treatment.

What is the rationale of this invigoration; this refreshing (Erfeischung, the Germans call it), of the nerve-centers? The latter are overpowered by the high temperature and toxæmia, and they stagger under the load, performing their work in a more or less indifferent manner, until at last they fail and the patient succumbs. As in minor degrees of nerve depression, fainting, for instance, the sudden impression of cold water upon the surface arouses the nerve-centers, so does, in the more pronounced and serious forms of adynamia, the same reflex influence stimulate them, and by continued access of cooled blood maintain the refreshing effect. The constant friction in the bath renders the peripheral nerve endings more sensitive, and the occasional effusion utilizes this condition for the furtherance of stimulating effects upon the nerve-centers. The result of the latter is evidenced not only by the improvement in the general appearance of the patient, by removal and prevention of apathy, dulness, somnolence, and even stupor, but also, as has been referred to above, by an enhancement of the functionating capacity of the various organs. I need refer only to the kidneys as an illustration of the effect upon its vaso-motor innervation. Next to the heart, the kidneys play the most important rôle in the maintenance of the integrity of the system in typhoid fever. The embarrassment of its functions in pronounced fever is evidenced by scantiness of the urine, its increased specific gravity, and the occasional presence of albumen. The gradual disappearance of these abnormal conditions is so positive a concomitant of decline of fever that the increase of the quantity of urine and its change to a paler hue was regarded by the ancients as a crisis. The effect of cold baths upon the hastening of the latter has been noted by even the earlier advocates of this mode of treatment. Even if the temperature resists their influence, the baths improve the condition of the urine, until the renal activity is increased even beyond the normal. The products of the increased oxidation are thus eliminated, as well as the toxic elements resulting from bacterial life and death

How far superior this treatment is to that by antipyretic medication is again demonstrated by their respective effect upon the kidneys. Antipyrin, for instance, diminishes the quantity of urine, as is shown by Tripier and Bouveret in a case of typhoid, in which baths and antipyrin were administered alternately.

To recapitulate, the rationale of the cold bath treatment of typhoid fever rests upon its meeting all the indications offered. A comparison with antipyretic medication brings out the value of the hydriatic method and elucidates certain points in its rationale.

THE *Monthly Sanitary Record* gives the following hints regarding the dangers of vacated houses: A good many people will soon be returning to their homes after their summer's vacation, and we would caution them about the danger of returning to a house which has been closed for some time, especially when the house is connected with the public sewer. In all probability the water-seal in the traps of the plumbing fixtures will have become evaporated, and the air from the sewer permitted to fill the house.

The germs of typhoid fever or other diseases, thrown into the public sewer, may possibly be carried into the house in this way. It has frequently happened that typhoid fever has broken out in a family recently returned from a vacation of several weeks, and in all probability the disease has been caused in this manner.

Families about to return to an unused house should have some one open all the doors and windows and thoroughly air the house for several days before their return, and also with buckets or hose to flush out the entire plumbing system of the house, thus filling all traps and cutting off communication with the sewer. Let no one neglect these simple precautions; they may possibly prevent the sickness or death of some member of your family.

BILLROTH, ON THE DANGERS OF CARBOLIC ACID.—The following letter of Dr. Th. Billroth, of Vienna, has been published: "I have lately seen four cases in which fingers which had suffered a most insignificant injury became gangrenous through the uncalled-for application of carbolic acid. Carbolic acid is now much less used in surgery than formerly; we have only gradually become acquainted with its dangers. The acid may not only cause inflammation and gangrene, but also blood poisoning, and so may even prove fatal. It is useful only in the hands of a skilful surgeon, and ought never to be used without his advice. The best lotion for recent injuries is the ordinary lead lotion, which can be bought at any chemist's. The best antidote in carbolic acid poisoning is soap, which should be taken immediately and repeatedly until all symptoms of poisoning have disappeared."—*Lancet.*

THE statistics for 1888 show that the number of births in France is still decreasing. Every year has shown a decrease, from 1884, when there were 937,758 births, to 1888, when there were but 882,639.

HYPNOTISM.

HYPNOTISM has never received in this country the consideration that it has on the other side of the water. There are many reasons for this. The practical, busy life of Americans inclines them to smile a little at whatever is of a transcendental o metaphysical nature, particularly if it be surrounded by an air of mystery. Universal prosperity and the absence of those extremes of wealth and poverty common to the continental nations, developing a high degree of nervous excitability among them, render us, as a nation, less susceptible to such neuroses, as catalepsy, trance and hypnotic sleep. Finally, successful, self-made nations, like individuals, are not apt to be the subjects of that credulity characteristic of those who are the sport of chance or the victims of misfortune; hence, as a nation, we are slow to believe and consequently slow to investigate. But the time has come when we should avail ourselves of the therapeutic benefits to be derived from the hypnotic methods of treatment if there is anything like truth in the many wonderful cures that have been reported. That there is such a thing as a hypnotic state, in which the patient is absolutely and entirely under the control of the operator, there can be no doubt. The only question is in regard to the percentage of hypnotizable people. The followers of the Nancy school assert that everybody can be more or less hypnotized; whereas the teachings of the Paris school are that the susceptibility to hypnotization is dependent somewhat upon a hysterical element in the subject. The definition of hypnotism, as given by Bernheim before the International Congress for Hypnotism, held at Paris, August, 1889, is a broad one. He says that the hypnotic state is that particular psychical state which may be produced and which increases, in varying degree, suggestibility—that is to say, the aptitude of being influenced by an idea that the brain receives and realizes. According to this definition there may be hypnotism without sleep, and Bernheim claims that he has obtained some remarkable results by simply telling the patient to close his eyes and then suggesting to him that such and such a trouble no longer exists.

In his work *De la Suggestion et de ses Applications à la Therapeutique* he states that only 5 per cent to 10 per cent of patients are refractory. When once the hypnotic sleep has been induced, by repeating to the patient, sometimes in a commanding, sometimes in a low, sleepy tone of voice, that he is no longer the subject of disease, rheumatism, gout, chronic constipation, diarrhœa, and general weakness can be cured. Not only are the functional diseases amenable to this treatment; postage stamps aided by suggestion have been made to raise blisters, burns produced by caustics have been made to heal with or without suppuration, the bad have been made good, and the deaf made to hear. The absurdity culminated when Tiebault declared that by simply suggesting to the pregnant woman in the hypnotic state, the fœtus could be physically educated in the womb! Bernheim believes that suggestion is the *vis medicatrix* in cases of purgation with bread pills, the induction of sleep by peroxide of hydrogen, the use of miraculous waters, as those of Lourdes, in massage, metallotherapy, hydrotherapy, electro-

therapy, secret ointments and granules, homœopathy, and even the suspension treatment of tabes. How often a hobby is in danger of being overridden!

There can be no doubt about some of the facts reported in connection with hypnotism, and to those who, like the writer, have seen it for themselves, the denial of it appears as ridiculous as its adoption for a panacea in all ills. The mind does exert a powerful influence over the body, and is itself in turn vigorously acted upon by variable states of the latter. And, again, we also know that when a perfectly healthy person is about falling to sleep, before all of the faculties have become obliterated, suggestions may be made and responses obtained. Somnambulism is a reality beyond cavil. Hence we see that certain strata of the mental constitution may retain their activity while the rest are held in abeyance. As a matter of fact, the inactivity of the higher faculties, such as the reason, causes an intensified activity of the lower, such as the perceptions and sensibilities. This is the result of increased concentration. The hearing is rendered more acute, the sight more piercing, and the perceptions more indelibly stamped upon the mind. Thus are explained the wonders of second sight and clairvoyancy, the medium being in a state to catch the slightest perceptible movement of the face and lips of those round about, however guarded they may be in testing his powers. In like manner the attention of the hypnotized person may be concentrated upon some particular part of his own body, and through the increased nerve excitability a change of some sort wrought therein. If a patient by suggestion can be made to feel no pain, the part may be kept at rest much in the same manner that opium would do, and so a cure brought about by the recuperative powers of nature. Such, in brief, is Bernheim's explanation of the therapeutical action of hypnotism.

According to Luys the hypnotic is similar to a paralytic, who, when brought to the asylum, may be told almost anything, and will believe it. How often we see such a one, after being told that he is a great monarch, a general or an ape, begin to act accordingly. Illusions, sensorial and emotional hallucinations, so characteristic of insanity, may be provoked by the operator in all hypnotic subjects. They may be given fixed ideas and wild conceptions, which will remain, and of which they have no notion whence they came. They may even be prolonged into the awakened state, and thus exert their influence for good or bad. Hypnotism is, therefore, closely allied to insanity, which is also proved by the evil effects that result from its too frequent application. Meynett, of Vienna, and Charcot, of Paris, have given it up as a therapeutic agent, simply for the reason that the benefits obtained from it do not counterbalance the weakening of the intellect, so likely to ensue. There is then a psycho-biology and a psycho-therapy. The forces of mind over body have long been the origin of the wonder-working miracles of charlatans, and as the fact is an undeniable one, it becomes scientific medicine to study it and employ it to the best advantage.

In the induction of the hypnotic sleep, the fixing of the eyes upon a brass ball or other bright object, according to Braid's method, is no longer considered necessary. Simply place the patient in a large arm chair, in a quiet, slightly darkened room; tell him not to resist the influence to sleep, and then repeat a dozen or more times some such phrases as "Now you are going to sleep; you are breathing slowly; your eyes are closing; you are almost asleep," etc., in a low monotonous tone of voice. If the patient is hypnotized a cataleptic state will be manifested when the arms are raised. Now the desired cure is suggested, and after a few moments the patient is awakened by simply telling him to awake. Such is the method employed by the Nancy school. At the Salpetriére the common method, as witnessed by the writer, was to press for several seconds upon the eyeballs. The *séances* should never last longer than fifteen or twenty minutes, and too much should not be expected at the beginning of the treatment.

Much has been written upon hypnotism, and the different methods of application can be found in the works of different authors, chief among which are those of Tiebault, Braid, Bernheim, Baierlacher, and Charcot. In the last number of the St. Louis *Weekly Medical Review* is a paper by Dr. Benno von Steinmetz, giving his own experience and the technique of the hypnotic suggestion. Of all the means employed to cure disease through the effects of the imagination, hypnotism is undoubtedly the most powerful. With certain precautions, mostly of a medico-legal character, it behooves American clinicians to study and become more familiar with this new therapeutic agent, and if there is anything really valuable and scientific in it, to rescue it from the hands of quacks and charlatans.

SALOL IN THE INTESTINAL DISORDERS OF CHILDREN.

SINCE we have learned the important rôle of microörganisms in the various disorders of the alimentary canal, the treatment of intestinal derangements has become more problematical and scientific, as well as more satisfactory. We have done with the routine administration of an opiate in all cases of diarrhœa, for though this treatment must needs be adopted at times, particularly when the causes are obscure, it frequently fails to give the desired results.

If our knowledge of the influences exercised by the bacteria in these diseases be correct, it is evident that their antiseptic treatment is the most rational and scientific. To rid the bowel of the cause of the affection is better, of course, than to merely combat the symptoms. But we said this treatment was at the same time problematic, and the truth of this is shown in the large number of antiseptics that are being daily tested with varying success.

The theory of the treatment being correct, it is necessary to secure an antiseptic whose action will be limited entirely to the destruction of the bacteria, that will be effective yet harmless to the patient and that can be easily and appropriately administered. Here is where the problem begins, and its solution is still the subject of extensive investigation.

In the last number of the *Archives of Pædiatrics*, Dr. Walter L. Carr, of New York, gives his experience with the use of salol in thirty-five cases of gastro-intestinal derangements in children. Salol or salicylate of phenol, administered by the mouth, is not changed until it reaches the small intestine; here the pancreatic juice splits it into salicylic acid and sulpho-phenol. Hence, as Lombard justly says, the action of the drug will not depend so much upon the dose as upon the quantity of pancreatic juice, as proved by the inert character of salol in the canal when the pancreatic duct is tied. Therefore, the administration of this antiseptic will have to be modified by the conditions of the pancreatic fluid. Perhaps a disregard of this fact is the cause of such varying results having been reported by numerous experiments. Some laud it to the skies, others find it of no avail whatever. It has been tried in all the disorders of the stomach and intestines in children. When the symptoms are those of acute gastro-enteritis, with vomiting of food, and the stools are loose, frequent and foul-smelling, the administration of salol, preferably alone or in combination with some inert powder, will be all that is necessary. When the stools are lumpy and streaked with bile, and particularly if bile appears in the vomit, mercury in the form of calomel will give quicker results when combined with the salol. In serous stools, dysentery, and severe colitis the salol will have to be reënforced with opium to relieve the tenesmus and check the discharges of blood. Hence salol exerts its best influence in the first stage of acute gastro-enteritis and in the more chronic forms of entero-colitis.

Dr. Carr recommends the dosage as follows: For children under six months one-half grain, between sixteen and eighteen months half a grain to a grain and a half, at two years a grain and a half to two grains. Other antiseptics besides salol, such as the sulpho-carbolate of zinc, naphthaline, and others of the new synthetical group, especially of the carbolic acid series, have been employed with quite favorable results. But its easy administration and up to the present time absence of toxic symptoms favor the use of salol, and will doubtless render it a popular intestinal antiseptic when the proper conditions for its administration are better known.

In all these respects, however, it is fully equalled by the sulpho-carbolates; which, moreover, do not depend on any intestinal chemistry for their efficiency.

Dr. Laplace has opened an office at 1617 Arch St.

Annotations.

THE IDEAL MAN.

An enthusiastic dentist, in a recent paper read before a Dakota dental society, after suggesting that the dentist of the future would make it his business to see that parents propagated healthy children, with sound teeth in good arches, warms up in his peroration thus: "The dentist of the future should be a man, priest, physician, and friend, all in one. Our bodies should be clean, our hearts pure, our brains clear, and our health sound. The ideal dentist will be the ideal man."

If the "dentist of the future" perform the functions of the other professional men referred to above, there will doubtless be a lamentable crowding in the different learned professions outside of dentistry. There is just a single ray of hope that sheds its ambient light over what is otherwise a gloomy and cheerless picture. The "ideal man" will never make his appearance, and consequently the ideal dentist will forever be a figment of the mind.

THE USE OF OYSTERS IN SUMMER.

Davaine stated that oysters spawn from the first days of June to the end of September; that in this hermaphrodite mollusk the ovules and embryos collect in the mantle, forming a sort of whitish pap, called milk or spawn, giving to the oyster a milky appearance. The fertility of an oyster is indefinite, and in one of ordinary dimensions one can count more than a million eggs and embryos.

M. Bouchon-Brandely, Director of Maritime Fish, and M. Henneguy, Chief of the Laboratory of Comparative Embryology of the College of France, think that it has not yet been shown that the consumption of oysters at the time of reproduction is injurious; the accidents which have been cited being probably due to other causes, while the habitual use of these mollusks, during the hot season, by the inhabitants at the centers of oyster culture, demonstrates the innocuity of this aliment.

On the other side, MM. Lalesque and Hameau call attention to the danger of using oysters in the hot season, when they have been transported to a distance from the beds and are eaten many days after leaving the beds.

Hameau further states that besides the ordinary colics and diarrhœas, he sees every year, from July to September, a peculiar form of poisoning, in persons who have eaten oysters which are still *ill from their accouchement.* These are neither in "white spawn" nor "black spawn;" but meager, non-lustrous and of a milky aspect, which remains for some time after the spawning is completed.

The symptoms of this poisoning are, the oysters having been eaten for dinner, nothing is shown of the morbid action until the end of the following night or the next morning; then, the patient is seized, somewhat brusquely, with violent intestinal colic, cold sweats, precordial anguish, nausea, with or without vomiting. This lasts some hours and ends

with free, greenish liquid evacuations, continuing four or five hours.

These cases are not very common; M. Hameau observing six or eight in a season. He believes that in this state the oyster contains a toxic alkaloid or ptomaine.

In commenting upon these cases, M. Grancher points to the fact of their paucity; the want of scientific rigor in the observation, as the toxic substance is indicated but not demonstrated, and that they point to the season following spawning as the dangerous one; while it is well known that in September the oyster is transported and eaten with impunity. The conclusion reached was that there were no grounds on which to pronounce the milky oyster toxic, and to interdict its sale and transportation. This conclusion was approved by the consulting committee, and the Minister of Marine issued a decree which permits the sale and transportation of oysters at any time.—*Journal d' Hygiene.*

ON another page will be found the programme of the coming Annual Meeting of the American Public Health Association. The session promises to be highly interesting and instructive, and one of its most important features will be the exhibition of sanitary goods and appliances in a neighboring hall. Here one will be able to study from a large collection of models and preparations the sanitary construction and arrangements of dwellings, schools, factories and workshops; matters of health pertaining to clothing and dress, and the preparation and preservation of food; sanitary engineering and the public health administration in cities and towns, and, finally, the laboratory, containing instruments of examination and precision, as microscopes, thermometers, hygrometers, biological apparatus, cultures, etc. The Red Cross Society will also have a section to itself.

Such an association, comprising as it does now over eight hundred members, all devoted, officially or otherwise, to its declared purpose, is in a position to exercise a most wholesome influence in the maintenance of public health. For the last sixteen years the Society has been meeting annually in the different cities of the United States and Canada. There will doubtless be a large attendance this year.

CALOMEL AS A DIURETIC.

IN Erb's clinic calomel has been effectively employed as a diuretic in renal dropsies. Polyuria begins on the third or fourth day, lasts five or six days; but is preceded by a diminution of the quantity during the first two days. When the maximum is reached, the calomel should be suspended. The specific gravity and albumen are diminished; there is no effect upon the heart. Diarrhœa is the only unpleasant manifestation; stomatitis may be prevented by chlor. potass.; salivation was absent. The dose was three grains three times daily, not exceeding a total of sixty grains. Diarrhœa must be met by tincture opii.—*Berl. klin. Wochensch.*, S. 2.

[Thus, we are returning step by step to the old time calomel medications of our forefathers.]

THERE is an editorial in the last number of the London *Lancet* calling attention to some weak points in medical education, that would be profitable for the American as well as the English schools to consider. In regard to the infectious fevers, for instance, the student rarely has an opportunity to study them, save during a special epidemic or after he has entered into practice for himself. Even when occasion is afforded to visit the special fever hospitals, the diseases cannot be watched throughout their entire course. This is a serious defect. Psychology and mental disease is another department of medicine in which the student frequently remains in blissful ignorance, until he is rudely startled as a practitioner by being suddenly called to give testimony in a court of law or sign a certificate for the detention of a supposed maniac in an asylum. These, as well as medico-legal questions, are rapidly being left entirely in the hands of experts by our rather defective methods of education; but every physician should be acquainted with this department of medicine, for many obvious reasons. Gynæcology and children's diseases are taught somewhat more practically than they used to be, but not yet as well as they might be. Some of these cases are the commonest in ordinary practice.

CHLORALAMID, to which we referred in a recent issue, appears to have come to stay. From reports gathered from various German clinics, Riegel's, at Giessen, Kup's, at Strasburg, and Mosler's, at Griefswald, its superiority to chloral is established. While it requires about 33 per cent. larger doses than the latter, it is said to be free from its unpleasant effects upon the heart, and, indeed, its action seems to be devoid of any positive after-effects upon the functions of the body.

It is regarded as valuable in nervous or senile agrypnia, in insomnia of special diseases, bronchial asthma, subacute rheumatism, and in other conditions not characterized by severe pain.

Chloralamid would appear to be one of our most valuable hypnotics; preferable to urethan and sulphonal, whose action is somewhat uncertain, and to paraldehyde whose odor is disagreeable. Still in some trying cases, especially in the psychoses, the change must be rung upon all our hypnotics.

CREASOTE in phthisis was administered in 1700 cases by Von Brunn (*Berl. klin. Wochensch.*, No. 8, 1889). The most favorable results were obtained in recent stationary cases of young people, due to a unilateral catarrh or infiltration of the apex. The gastric digestion was first improved, and later the respiratory symptoms; a gradual diminution and even disappearance of bacilli was noticed; the physical signs and fever were favorably influenced. Von Brunn ordered creasote in wine or pills with opium, and inhalations.

Szendiak (*Schmidt's Jahrb.*. B. 218, p. 145) treated 175 cases with favorable effect in 42 per cent., especially upon the cough and expectoration. In many cases the general condition improved.

WHILE the scholarly address of Dr. Moore contains nothing directly appertaining to the domain of practical medicine, we publish it as an illustration of the best form of an address to an intelligent, non-professional audience. Dr. Moore is one of those who can accept deductions of modern science and yet retain his religious faith; he accepts evolution and still believes that even it had a first cause; and in this view he assuredly has the support of the vast majority of intelligent men in the medical profession.

RESTORATION of liver structure, after removal of large portions, has been noticed by Ponfick, who ablated under antiseptic precautions parts of the liver in hundreds of animals. Many of the latter lived a year and longer with comfort. A massive formation of young liver tissue, somewhat differing from the original, begins in a few days and reaches its completion in a few weeks, so that almost the entire portion, more than double of what has been removed, is reproduced.

—*Cent. für Med. Wissensch.*, No. 35, 1889.

CARBONIC ACID has recently been administered by Dr. H. Weber (*Berl. klin. Wochensch.*, Sept. 2) to a number of phthisical patients, ten of whose histories he furnishes. Weber orders bicarbonate of potassium, one teaspoonful, to be taken immediately after a glass of water containing twelve drops muriatic acid (diluted?) has been sipped. These remedies are administered before meals. He claims that all his patients experienced great relief from cough and improvement of their respiration, as well as of the appetite.

Letters to the Editor.

VIRGINIA LETTER.

I SENT you, some time ago, a letter from Montgomery White, about the springs in that vicinity. Soon after I left there, and for the last month, have been at the most comfortable hotel in these mountains, the Blue Ridge Springs, under the management of Mr. Phil. Brown, a most estimable and able manager and proprietor of this hotel. In the evening of September 3, I came in to the meeting of the Medical Society of Virginia, which began its twentieth session in the opera house of Roanoke last evening. The meeting was called to order by the President, Dr. E. W. Rowe, of Orange Court House. After prayer by the Rev. W. H. Meade, of St. John's Episcopal Church, of this city, an address of welcome was delivered by Dr. A. L. Koiner. At the conclusion of Dr. Koiner's address, Dr. Rowe, the President, responded briefly on behalf of the Society.

The Secretary, Dr. Edwards, read the list of applicants for membership, forty-eight in number.

Dr. Thomas J. Moore was introduced, and delivered the annual address. His subject, Man and His Development, was handled in a masterly manner, and was entertaining and instructive to a degree rarely equalled and never surpassed, in our opinion.

Wednesday, September 4.—The Society reassembled this morning at 10 A.M., and after going through the business part of the meeting there was still half an hour, when Dr. Wyeth, of New York, the able surgeon, was invited to read a paper on the subject of Cocaine. He began with a brief history of the drug, and the part which was taken by the American physicians and surgeons in its introduction. He had employed it now for about five years in various amputations of the fingers, toes, and also in the removal of small tumors, warts, nerves, etc. His method was to employ a four per cent. solution, never using more than a drachm hypodermically, either in the line of the wound or neighborhood. To prevent its toxic symptoms, he always employed a ligature or tourniquet, adopting "Corning's method," and when the operation was finished he took care that the material should not be allowed to enter the circulation suddenly, but gradually withdrew the agent in a slow matter by loosening the tourniquet. Dr. Wyeth did not like it in children, nor did he advise it in extensive operations, but he considered it one of the most valuable agents to the surgeon after antiseptics.

Dr. McGuire, of Richmond, then followed with some remarks, stating his experience especially in circumcision and other operations of a minor character, and stating he had employed it quite extensively and with satisfaction, yet he desired to impress the gentlemen with caution, stating that he had one or two cases in which the patients had been nigh unto death, and were only saved by the use of the nitrite of amyl. He also mentioned Dr. Sims', of Philadelphia, case of death from the injection of a twenty per cent. solution in the urethra. He considers there is a cocaine habit like the morphine, alcoholic, or opium habit. These cases are, we think, very rare, and some of the most able physicians have met with not more than one or two during the five years' use. This subject is well discussed in the new edition of Dr. Turnbull's "Manual of Anæsthetics," now passing through the press, advance sheets of which we have seen by the politeness of the publishers, Messrs. Blakiston, Son & Co., Phila.

Following the paper of Dr. Wyeth came the address of the President, Dr. E. W. Rowe, on the subject of Reform in the Profession. It was filled with witty remarks and many interesting anecdotes, and many wise sayings and most useful suggestions, both to young and old.

It is most wonderful, the power of recuperation of these Virginia gentlemen. Consider the sufferings, poverty, and hardships which they endured, and yet their Society nearly numbers a thousand, and they themselves are advancing their profession, and are a credit to it by their learning and devotion; a bright example to their brethren everywhere.

After the address of the President and its recommendations had been disposed of, the subject of Croupous Pneumonia was called for discussion, and opened with a paper by Dr. B. L. Winston, of Hanover, C. H.; also, a paper by Dr. H. C. Becket, of Scottsbury, Va., followed by a third paper by Dr. L. G. Pedigo, of Roanoke, entitled, Sedative Doses of Calomel in Croupous Pneumonia.

The night session was taken up with Practical Reports on Advances in the Eight Departments of the Medical Sciences. A banquet was given at the Roanoke Hotel.

ROANOKE, VA., Sept. 3, 1889.

Society Notes.

MISSISSIPPI VALLEY MEDICAL SOCIETY.

THE Mississippi Valley Medical Association held its fifteenth annual meeting at Evansville, Indiana, beginning September 10. The meeting was a most pleasant and profitable one, the papers presented numbering one hundred or more. The discussions were participated in by most of the members, and elicited a number of new and valuable ideas.

The meeting was ably presided over by Dr. George F. Cook, of Indianapolis. Owing to the full programme, he excused himself from a formal address, but opened the session with a few well-chosen remarks. Dr. R. L. Thomson, of St. Louis, was at the Secretary's post, and Dr. A. M. Owen, of Evansville, as Chairman of the Committee of Arrangements, covered himself and the city with glory. A number of visiting doctors, far from the Mississippi Valley, were present, among them Dr. George H. Rohé, of Baltimore, and Dr. W. C. Wile, of Danbury, Conn. In an address, the former chanced to mention that his native city was the birthplace of the "Star-Spangled Banner." He was unanimously requested, in one united shout, to "sing it." The band took up the strain, and then followed a very patriotic exhibition.

The social occasions were many, and to some, almost overwhelming. The evening of the first day, a banquet was given at Garvin Park. This was attended by many invited guests, and the whole affair, under the leadership of the witty Dr. I. N. Love, of St. Louis, as toast-master, was highly enjoyable. A complimentary concert and ball brought together the élite of the city and neighboring towns, and the members of the Association were made to feel that naught was too exalted which would add to their pleasure. An excursion occupied the third evening, and besides these were several private entertainments; so the meeting was not only successful in point of numbers, papers read, ideas advanced, discussion aroused, but in the social point of view, which, after all, adds the needed spice to these gatherings. The Committee on Nominations reported by their Chairman, Dr. I. N. Love, as follows: President, Dr. Joseph M. Matthews, Louisville; First Vice-President, Dr. C. R. Earley, Pennsylvania; Second Vice-President, Dr. T. B. Harvey, Indianapolis; Permanent Secretary, Dr. E. S. McKee, Cincinnati; Treasurer, Dr. W. C. Chapman, Toledo, O. Louisville the place of next meeting, September, 1890; Dr. I. N. Bloom, of Louisville, Chairman Committee of Arrangements.

DR. H. C. DALTON, of St. Louis, Superintendent of the City Hospital, read an interesting paper, entitled:

IS SENN'S GAS-TEST INFALLIBLE, AND ALWAYS DEVOID OF DANGER?

He reported a case of gun-shot wound of the abdomen, the ball passing into the thorax in left axillary line, between the seventh and eighth ribs. There were no symptoms of abdominal injury, but from the direction of the ball he suspected that the abdominal cavity had been penetrated. He resected three inches of the seventh rib, and found a hole through the diaphragm, three inches from the thoracic wall. He introduced a glass tube and applied the gas test, but received negative results. Laparotomy was not performed. The patient came near dying from interference with respiration, due to the enormously gaseous-distended intestines pressing upon the diaphragm. At the autopsy, eighteen hours after death, two holes were found in greater curvature of the stomach, four inches below the cardia, the hole of exit being a half inch below hole of entrance. The lower-third of the stomach was filled with semi-solid food, which had securely plugged up the bullet-holes during the administration of the gas, and prevented its escape into the peritoneal cavity, that accounting for the failure of the test.

He concluded, if semi-solid food would cause the test to fail, semi-solid fæces would do the same thing, and hence the claim that the test is infallible is untenable.

He also reported a case in which the test gave affirmative results, the gas escaping and igniting freely. Laparotomy was performed, and twelve holes were closed by the Lembert suture: two in the cæcum, six in the small intestines, three in the mesentery and one at the hole of entrance. Owing to the gaseous extension, difficulty was experienced in returning the intestines to the cavity and closing the wound. In the attempt, the firm pressure caused the holes to burst in several places, flooding the peritoneum and obliging the peritoneal toilet to be done *de novo*.

He thinks this, together with the excessive gaseous pressure upon the diaphragm after the closure of the abdomen, adds to the shock, and hence he argues that the method is not devoid of danger. The patient died eighteen hours after the operation.

EARLY DIAGNOSIS OF CHRONIC KIDNEY LESIONS,

was the subject of a paper by DR. C. S. BOND, of Richmond, Ind. This paper was really the report of a committee of one appointed at St. Louis last year. In conclusion, he gave the following summary:

Albumen in the urine probably always means disease somewhere in the body. In so-called physiological quantities, it may be referred to disease removed from the kidneys, and the cause as transient. In pathological quantities, it signifies either inflammation external to the kidneys, or a lesion of these organs. Many patients, with evident kidney lesions, do not pass albumen. Albumen is inconstant, and bears no relation to the extent of the lesion, but when present, must be respected as a prominent factor in diagnosis. It generally makes its appearance a long time after other well-marked symptoms have existed, and the disease is grave when it exists in pathological quantities, and the symptoms, therefore, should not be awaited.

Casts bear an intimate relation to albumen, but appear later. They are strong proof of renal inflammation, as they carry, usually, a part of its epithelium. Differentiation of the varieties of kidney lesions can often be made from this fact, but they, like albumen, are inconstant. Many patients do not pass them at all, and they always appear too late as a factor in early diagnosis.

The specific gravity of the urine is not to be relied upon, unless the mean specific gravity of many specimens is taken for known quantities of urine for twenty-four hours. This would mean a small amount of urea passed within the time, since it is the dominant salt eliminated; therefore, why not test for urea at once?

Some outward manifestations of ill-health, perhaps continued for years, always precede the passing of albumen and casts. These symptoms are in common with well-marked kidney lesions, and are not due to other discoverable physical causes. Cases, often without a change in these symptoms for years, begin passing albumen and casts. It is fair, therefore, to assume that the symptoms referred to are the result of some common cause which precedes the pronounced kidney lesions. This common cause seems to be something which produces extension and often inflammation of serous membranes, which at the same time, or remotely, involves the kidneys. What this case is we at present only conjecture, but many of its pathological effects might be turned to advantage in early diagnosis. Urea is excreted in abnormally small quantities in cases of well-marked kidney lesions. It is also so excreted in cases having the prominent physical symptoms without albumen and casts. It is interchangeable as a means of diagnosis with the outward signs of the disease, *i. e.*, a knowledge of ill-health being also a knowledge of the amount of urea passed and *vice versa*. Urea is excreted in small quantities for months, and often years, before albumen and casts appear, therefore a knowledge of this excretion is invaluable as a diagnostic sign of early lesion.

The diminished quantity of urea eliminated is the result of constitutional disturbances, which precede the local lesion for long intervals of time. Active treatment, which would be harmful in other diseases having some symptoms in common, will identify this, generally relieves, and frequently apparently cures.

TREATMENT OF THE INSANE IN RELATION TO SCIENCE

was the subject of a paper by Dr. Orpheus Evarts, Superintendent of the College Hill Cincinnati Sanitarium. This paper was very laudatory of the modern treatment. He did not believe insanity was a disease of civilization. It was a disordered brain. All who have brains are liable to this disease.

THE FORMATION OF ARTIFICIAL URINARY CANAL

was the subjected treated by Dr. W. N. Wishard, of Indianapolis.

De. Wm. C. Wile, of Danbury, Conn., in discussing this paper described an operation for this object which was original with himself. The paper was further discussed by Dr. C. Frank Lydston, of Chicago.

PURULENT CONJUNCTIVITIS

was the title of a paper by Dr. D. A. Thompson, of Indianapolis. He insisted on cleanliness, washing the eye, if necessary, every half hour with a saturated solution of boracic acid in water. He also used the nitrate of silver, but had not met with success in the use of bichloride of mercury. Discussed by Dr. Knapp, of Evansville.

SYMPATHETIC DISEASES OF THE EYES FROM INFLAMMATION OF THE NASAL PASSAGES

was the subject of a paper by Dr. Francis Bowling, of Cincinnati. He thought the medical attendant was too prone to treat the eye disease and overlook the disease in the nose. He should recognize the fact that the origin of the disease is in the nose and not in the eye, and shape his treatment accordingly.

THE CAUTERY *vs.* THE SNARE

was the subject treated by Dr. E. R. Thompson, of Indianapolis.

Dr. Geo. W. Ryan, of Cincinnati, read a paper entitled

THE ORTHOPEDICS OF INFANTILE PARALYSIS.

The author reached the following conclusions:

1. That orthopedic treatment, in conjunction with local treatment of muscles, is useful in all children who have arrived at the walking age. It gives support and prevents deformity.

2. That it tends to preserve, in a measure, the proper balance between antagonistic groups of muscles by aiding the weakened group, and restraining the normal ones.

3. That by this means, the paralytic groups are given the benefit of any movement of which they are capable, and in this way they can get exercise.

4. That it certainly can correct deformity.

5. That a heavy appliance, or one adjusted by lacing bands to the leg or thigh, does more harm than good.

6. That such measures are a necessity in the after treatment of divided tendons or muscles.

7. That in most contractions it is better to divide them than to stretch them.

STERILITY IN WOMAN, ITS ETIOLOGY AND TREATMENT

was the title of a paper by Dr. E. S. McKee, of Cincinnati.

The author found the subject a difficult one. He thought the most common cause of sterility was intra-uterine disease, and chronic endo-metritis its general manifestation. Inflammations of the pelvic peritoneum and of the parametria or their consequences are a frequent origin. Three things must be determined, are spermatozoa in semen, do they get into the utero-cervical canal, do the vaginal secretions poison the spermatozoa? Sterility in man must be eliminated before seeking the causes of childless marriage in the wife. Gross claimed that one out of six sterile marriages were the fault of the husband, and Kehrer claimed one-third, and the cause of the barrenness was gonorrhœa. The habits of the wealthy

diminish fertility, while those of the poorer classes seem to favor it. The injurious effect of excessive fat in women, as regards childbearing, is generally admitted. The prospects of offspring will depend more on the menses than the flesh, amenorrhœic fat women being usually sterile. The prevalence of spasmodic dysmenorrhœa among sterile women, about two out of five cases, leads to a belief that this condition has some influence upon sterility. Gonorrhœa is an important factor. The reflux of semen is not so important a cause as supposed; the mucous discharge of the glands of Cowper and Duvernay are often mistaken for semen. A Chicago professor has found in that city that the hair on the mons veneris of sterile women is straight. He does not advise curling the hair as a cure for sterility, however. Sexual incompatibility is well known to exist. Sterility may be occasioned, when necessary, by obliterating the ends of the Fallopian tubes with the thermocautery. Some authors claim that consanguineous marriages are sterile. Darwin finds these slightly more fertile than non-consanguineous. He thinks this fact is because such marriages take place where there are large groups of cousins, and fertility becomes hereditary.

The cure of sterility is one of the difficult tasks of gynæcology. Our imperfect knowledge of the cause is the origin of our trouble when we come to treatment. Women addicted to alcohol have become pregnant upon becoming teetotalists. Obesity is treated by a rigid diet, the menses increase as the obesity decreases, and the patient frequently conceives. A hyperæsthetic condition of the vagina sometimes necessitates anæsthetization. The radical treatment of endometritis by curetting is frequently followed by conception. The author has had good results from a solution of perchloride of iron one part, glycerin three parts, painted in the cervical canal in chronic endometritis. Constitutional treatment is often effective. Outerbridge has devised a new instrument for the cure of sterility. It consists of a steel wire, gold or silver plated, with a slight eversion at one end, with the other bent at right angles. This is inserted into the cervix. Catherization of the Fallopian tubes is sometimes effective. Sea-bathing, residence at watering places, and the use of mineral waters has a very beneficial effect on many stubborn cases. The crystalline phosphide of zinc, one-eighth grain morning and evening, is highly recommended. Tea drinking and the ingestion of tannin and sulphur are to be avoided. Belladonna has the reputation of promoting conception. According to Cohnstein, there are times with every woman which might be called the period of predilection for fecundation. If reflux of semen be the trouble, the hips should be elevated during coition, the penis allowed to remain as long as possible in the vagina. The taking of the knee-chest position immediately after coitus is recommended, and perineoraphy is sometimes necessary. As a last resort artificial impregnation is necessary in otherwise hopeless cases. It is disagreeable to all concerned, but there are no real moral reasons against it. An alkaline vaginal injection of phosphate of soda should precede the operation to neutralize the vaginal secretions. Sexual intercourse should take place; the syringe, new, free from infecting matter, should be at the exact bodily temperature, the semen taken up carefully, the nozzle inserted clear to the fundus and the fluid injected. A extensive bibliography accompanied this paper.

CHRONIC TONSILLITIS

was the subject of a paper by Dr. Fletcher Ingalls, of Chicago. He insisted on non-subjecting children to the torture of removal of the tonsils without the benefit of an anæsthetic. Discussed by Drs. Wm. Porter, of St. Louis, and E. R. Lewis, of Indianapolis.

Dr. I. N. Bloom, of Louisville, reported two cases of

AMPUTATION OF THE PENIS,

and discussed the subject.

THE TREATMENT OF PULMONARY PHTHISIS

was the subject of a paper by Dr. C. F. McCahan, of Chattanooga, Tenn. He thought when there were present symptoms of the disease without inflammation, the majority of the cases are capable of cure. He reviewed the treatment of phthisis since the discovery of Koch, and related his personal experience. He had phthisis in 1882 (but didn't look as if he had) and had recovered. In treatment, we have returned to nutrition and pure air. We should always let the patient have a thread of hope, though it may be a false one. The care of the stomach was the great thing. Give as few medicines as possible, so as to keep the stomach in good order. The hygienic treatment should take the precedence to the medical. As for health resorts, he favored Asheville and Aiken.

DIFFERENTIAL RESPIRATION

was the subject of a paper by Dr. F. C. Wilson, of Louisville, who showed his bellows for this purpose.

CONTAGIOUSNESS OF PHTHISIS.

The report of the committee appointed last year was made by Dr. Wm. Porter, of St. Louis, Mo. He thought the word portageous was more accurate than contagious. He thinks the evidences of transmissibility in tuberculosis are conclusive. Two hundred and fifty-one English physicians in active practice in families have replied in favor of the theory of the transmissibility of tuberculosis. The New York Board of Health has passed resolutions which acknowledge this contagion. The fact has been published that there have been no cases of tuberculosis among the nurses and house physicians at Brompton Hospital. This is true on account of the excellent hygiene of that institution, and does not prove the non-contagiousness of the disease.

It has been written that there was no tuberculosis among the North American Indians, and but little among the early settlers of New England. One hundred years ago the climate of New York was thought to be good for tuberculosis by Europeans, who sent their patients there; then, later, the prairies of Illinois were lauded for the same purpose; then, later, the mountains of Colorado and the valleys of California. He emphasized the fact that the care of

localities used as resorts for consumptives was very important, as they do not get infected with the disease. He recommended that consumptive patients use cuspidors in which there was a 1–1000 solution of bichloride, as it has been demonstrated that a weaker solution has not always the potency sufficient to destroy the bacilli. He recommended as a prophylactic measure to the spread of tuberculosis the most careful inspection of the meat and milk. He considered the future of this subject a bright one.

TUBERCULAR PERITONITIS, WITH REPORT OF CASE, was the title of a paper by DR. EDWIN RICKETTS, of Cincinnati, in which he advocates the operative treatment in this trouble.

DR. THEODORE POTTER, of Indianapolis, said that no one doubted that the tubercular bacillus caused the disease. He cannot doubt this any more than we doubt the laws of gravitation. We must remember that tuberculosis is a local disease just as much as is an abscess. It may become general, but it is not so in the beginning; and only accidentally becomes so. Tuberculosis is not generally hereditary. We are now on more positive and definite ground in regard to this disease than ever before. The paper was further discussed by DRS. EARLEY, Pennsylvania; CUTTER, New York; BRAYTON, Indianapolis; CHAPMAN, Toledo; MYERS, Fort Wayne; REYNOLDS, Louisville; MCCAHAN, Chattanooga; RICKETTS, Cincinnati; PORTER, St. Louis.

Book Reviews.

TRANSACTIONS OF THE NEW YORK STATE MEDICAL ASSOCIATION FOR THE YEAR 1888. Volume V. Edited for the Association by ALFRED LUDLOW CARROLL, M.D. Pp. 610. New York: J. H. Vail & Co., 1889.

The present volume is full of interesting papers and practical discussions. The reports of the committees appointed to investigate certain special questions are replete with valuable suggestions and admirably presented. The President, Dr. John Cronyn, introduced into his annual address some pertinent hints in regard to preserving the proper deferential relations between the medical profession and the public. He justly decried the audacity with which newspaper hack-writers and irresponsible laymen attempt to criticize medical matters before the masses. The ministry and the legal profession, though occupying a less responsible position in regard to so serious a matter as life and death, are far less exposed to the hostile attacks of ignorance and superstition. Medical men should protect the interests of their profession by preserving a silence and well-balanced neutrality in regard to matters of doubt, and a positiveness born of knowledge in regard to matters positive.

The Address on Surgery, by William H. Carmalt, M.D., is a capital exposé of the treatment of carcinoma, and is appropriately followed by the highly instructive report of the committee and discussion upon neoplasmata in general.

A delicious sauce to the more solid viands is Dr. John Shrady's Address on Medicine, in which are vividly portrayed some of the curious customs of the medical lights of New York City during the early part of the present century. Their brief biography, peculiar manners, methods of treatment, styles of dress, as well as their relations with the people of the time, are presented in a way that is highly literary and picturesque. To our taste, this essay is the gem of the Transactions.

Among the other notable addresses we may mention The Origin and Medical Treatment of Uric Acid Calculi of the Kidney, by John Garlock, M.D.; Diphtheritic Paralysis, by J. Lewis Smith, M.D.; the Address on Obstetric Medicine, by George Tucker Harrison, M.D., followed by a discussion on Puerperal Septicæmia; and Seaside Hospitals for Sick Children, by Charles A. Leale, M.D.

We were intensely entertained by the discussion on Nosography. That some more positive basis than we now have for the classification and naming of disease is needed goes without saying. An anatomical basis is out of the question almost, as one of the gentlemen justly declared, since disease is not a fixed entity but a process. In the absence of more extended knowledge we will doubtless have to put up with such unmeaning phrases as "Basedow's disease" or "Addison's disease" for a time, at least. Many shrewd suggestions, amusing illustrations, and acute criticisms are brought out in this discussion, and while it shows the desire of the profession for a higher scientific stand, it portrays the lamentable weakness of scientific medicine even at this advanced age.

Several memoirs and technical reports close this well-edited volume of the Transactions of the New York State Medical Association for the last year.

Pamphlets.

Retrospection of the Medical Society of New York, with some suggestions as to its improvement. President's address. By H. Genet Taylor, A.M., M.D., Camden, N. J. From the Transactions of the Medical Society of New Jersey. L. J. Hardham, Newark, N. J., 1889.

The Effect of the Entrance of Air into the Circulation. By H. A. Hare, M.D., Demonstrator of Therapeutics and Instructor in Physical Diagnosis in the University of Pennsylvania. Reprint from the *Therapeutic Gazette* for September 16, 1889. Geo. S. Davis, Detroit, Mich., 1889.

The Hydrotherapeutic Treatment of Typhoid Fever. By G. C. Smythe A.M., M.D., Greencastle, Ind. Reprint from Transactions of Indiana State Medical Society, 1889.

This is a practical and timely p per founded upon statistics.

A Report on the Insane Asylums of Missouri. By Frank C. Hoyt, M.D., Third Assistant and Pathologist to State Lunatic Asylum, No. 2, St. Joseph, Missouri. Reprint from Saint Joseph *Medical Herald*, St. Joseph, Missouri.

Terebene; Its Medicinal Uses and Value. By Sebastian J. Wimmer, A.M., M.D., St. Mary's, Pa. Reprint from the New York *Medical Journal* for February 9, 1889.

The Senses, Five or Seven. Paper read before the Academy of Anthropology, by Wm. M. McLaury, M.D., at the regular meeting, held at Cooper Union, New York, March 5, 1889.

A FIFTEENTH STREET lady made some hair dye from a newspaper recipe, and her hair turned a bright blue after she had applied the liquid.

The Medical Digest.

BOWIE makes a favorable report in the *Lancet* upon the Weigert method of treating phthisis.

A NEW artificial tympanic membrane has been produced by Mr. Cousins. It is made of compressed cotton, and is the shape of a hat.

IN the *Indian Medical Gazette* is reported the case of a native porter who slipped and fell while carrying a load, rupturing the right phrenic nerve, causing instant death.

FOOTE, in the *American Journal of the Medical Sciences*, concludes that the best disinfectants for the feces are bichloride of mercury with hydrochloric acid or potassium permanganate, and the chloride of lime. The disinfectant should be stirred with the feces and allowed to stand at least four hours.

CHOLERA bacilli die in milk when it sours; the extreme vitality being six days. They live in butter for a month, but only a day in cheese curds. Typhoid bacilli live much longer; in milk, from thirty-five to forty-eight days; in butter, three weeks; in whey and cheese, only three days. Tubercle bacilli live in milk from four to twenty-eight days; in butter, four weeks; in cheese, thirty-two days and more.—*Lancet.*

HAVILAND pointed out, twenty years ago, that cancer was most prevalent in the low river lands, which were liable to overflow, and rare along the watersheds. In several river districts a small proportion of cases occurred, and in these it was found that the chalk formation appeared at the surface and formed the rock base, while under the loose soil of those districts showing a high cancer mortality were the retentive clays. While every district of South and every county of North Britain shows an increasing ratio of cancer deaths, the English lake district possesses the conditions of soil and climate least conducive to the growth of this disease, which has not advanced here in twenty years.—*Lancet.*

DR. J. A. WARD asks in regard to the "Concealed Hemorrhage at the Fifth Month of Pregnancy," reported in his letter to editor in the issue of September 7, 1889: "Now was this a case of placenta previa, in which the after-birth covered the entire mouth of the womb, or was it a case of extra-uterine pregnancy, in which the placenta found lodgment in the cervix or upon the os internum, thereby sealing up the cavity of the womb, the fœtus remaining in the expanded neck of the womb and vagina until the fifth month of pregnancy? How was the after-birth separated from the parts of the mother, so as to cause a hemorrhage sufficient to fill the cavity of the womb with more than a gallon of blood within three weeks and yet prevent a single drop from escaping externally? Was it by upward pressure or lateral expansion of the over-extended cervix?"

Medical News and Miscellany.

A PASTEUR institute has been founded at Rome.

PROFESSOR H. C. CHAPMAN returns from Bar Harbor on September 30.

PROFESSOR ANDERS opens the Medico-Chirurgical course at noon on September 30.

CHOLERA has broken out furiously at Hyderabad, beginning at a Hindoo wedding party.

A CORNED-BEEF sandwich nearly killed Frank C. Douds, of New Castle. The beef had spoiled.

PROFESSOR KEEN opens the Winter Term at the Jefferson College on the evening of September 30.

DR. JOSEPH BEALE, formerly Surgeon-General U. S. Navy, died in Philadelphia on September 23.

DR. FISLER, of Lebanon, is at the Medico-Chirurgical Hospital, where he is being treated for amnesic aphasia.

LATE advices show that the cholera is less violent at Bagdad, though it still spreads along the Euphrates.

DR. S. WEIR MITCHELL has been elected President of the Congress of American Physicians, to be held in 1892.

MORE women are cremated than men. The reason alleged is that men most respect the wishes of their dying wives.

PROFESSOR E. E. MONTGOMERY has been elected President of the Society of American Gynecologists and Obstetricians.

DR. BICKERS has left the Medico-Chirurgical Hospital, where he has passed through a severe attack of pernicious remittent fever.

A NEW medical college has been started in Glasgow, and those who are not professors, but think they ought to be, are very mad about it.

WITH the September number, the editorship of *The Microscope* passes into the hands of Dr. Alfred C. Stokes. May success attend his efforts.

DR. CARL FORSTEAND, of Stockholm, a distinguished Swedish physician, is in this country making a general investigation of medical science in the United States.

LOS ANGELES is becoming unhealthy from the defects in her sewerage. This is a pity, as she would otherwise become one of the most popular sanitaria in the world.

LAST week there were in Philadelphia 20 deaths from typhoid fever, 5 from scarlatina, 9 from diphtheria, 4 from croup, 12 from cholera-infantum, and 44 from consumption.

WE have had analyses made of a number of the fluid extracts in the market. Our readers will be somewhat surprised when they know the results, which are not yet ready for publication.

BETWEEN sixty and one hundred guests at a banquet in the new armory of the Woodstock Guards at Birmingham, Ala., were poisoned by eating ice cream, and a number are still seriously ill.

IT is said—and denied—that pressure is being brought to bear upon Professor Leidy to induce him to resign his chair at the University of Pennsylvania. There are others in the faculty who could be better spared.

THE sun-cure of Tyrol might prove a more lasting novelty than the elixir. It consists in drinking fermented grape-juice till you can't see the bottle; then sleeping in the sun till the effect passes off, and then repeating the process until the cure is attained.

DR. EPHRAIM CUTTER, of New York, at New Castle demonstrated and read before the British Association for the Advancement of Science. On the 26th of this month he reads two papers before the London Society of Science, Letters, and Art.

THE DIETETIC GAZETTE will henceforth be issued as a monthly. It is believed that this step is fully warranted by the importance of the subject, and the growing interest in it. The GAZETTE is the only journal in the world devoted exclusively to this subject.

THE death-rate in Philadelphia last year was reckoned by the Board of Health at 20.04 per thousand of population. This was less than the rate of the preceding year. For the first half of 1889 the death-rate was slightly increased. Yet, in London, during the same period, it was only 17.8 per thousand.

"WITH few exceptions, life insurance companies refuse to accept the services of homœopathic physicians as examiners of applicants for policies," is the complaint of a homœopathic journal. A few years ago it was claimed that the companies gave better rates to persons enjoying homœopathic treatment, but it was found that this was only the case with the Homœopathic Life Insurance Company, which became bankrupt. Both facts are suggestive.

CORRECTION.—By an accidental falling of the types in their final arrangement into columns the printer has caused a few errors in Dr. E. E. Hamilton's article, The Nasal Cavities, published August 17, 1889. Note the following corrections: Read after *admission of*, page 366, line 34, *odorous particles to the sentient surfaces; that the glands and nerve filaments should be healthy; that the membrane should be moist and not clogged with unhealthy mucus, and that the nerve itself should be unimpaired in function. Minute particles of odorous matter, etc.*, . . . *ciliated epithelium.*

It is thicker in places, particularly over the inferior turbinated bones. This thickening, etc., . . . *with the ciliated ganglion. This connection is of importance, etc.*, . . . *neuroses of nasal origin.*

CHICAGO is moving the earth to secure the World's Fair, and is actively enlisting the other Western cities in her behalf. Meanwhile, New York has apparently not yet made up her mind that she really wants it, though she evidently believes that, if she does, all she has to do is to stretch out her hand and take it. Philadelphia doesn't think of it at all; her great Centennial having exhausted the stock of her vitality, which will require a century of somnolence to recuperate.

PROGRAMME of the Seventeenth Annual Meeting of the American Public Health Association, to be held in the Hall of the Brooklyn Institute, October 22, 23, 24, 25. Addresses of Welcome by Hon. Alfred C. Chapin, Mayor, and Alexander Hutchins, M. D., and the following topics for consideration: The Causes and Prevention of Infant Mortality, Railway Sanitation, Steamship Sanitation, Methods of Scientific Cooking, Yellow Fever, The Prevention and Restriction of Tuberculosis in Man, Methods of Prevention of Diphtheria, with results of such Methods, How far should Health Authorities be permitted to apply known Preventive Measures for the control of Diphtheria, Compulsory Vaccination, Sanitation of Asylums, Prisons, Jails, and other Eleemosynary Institutions.

There will be an exhibition of sanitary goods and appliances in another large hall close by.

To Contributors and Correspondents.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from September 8, 1889, to September 21, 1889.

SMITH, ANDREW K., Colonel and Surgeon, Leave of absence for fourteen days on surgeons certificate of disability is granted by direction of acting Secretary of War. Par. 1, S. O. 214, A. G. O., September 14, 1889.

STERNBERG, GEORGE M., Major and Surgeon. Having completed the duties assigned him in War Department order dated February 4, 1889, is reassigned, by direction of the acting Secretary of War, to duty as attending surgeon and examiner of recruits at Baltimore, Md. Par. 12, S. O. 218, A. G. O., September 19, 1889.

Changes in the Medical Corps of the United States Navy for the week ending September 21, 1889.

BEARDSLEY, G. S., Medical Inspector. Granted six months' leave, with permission to go abroad.

RUTH, M. L., Surgeon. Order granting furlough revoked and placed on waiting orders.

Medical Director HUDSON, Medical Inspector WOODS, and Surgeon DICKINSON will continue as president and members of an Examining Board for examination of applicants for the position of Assistant Surgeons in the Navy at San Francisco, Cal., until June 30, 1990.

Medical Index.

We purpose on this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Address before the graduating class of the University of Maryland. delivered April 8, 1889, by William Kirkus, M.A., LL.D. Maryland Medical Journal, September 14, 1889.

Analogy of summer diarrhœa and cholera, by Sir William Moore, K.C.L.E., etc. *Ibid.*

Antipyrin, antifebrin, and phenacetin as antipyretics, notes on the comparative value of, Crombie. Indian Medical Gazette, July, 1889.

Aortic disease of the heart, by Graham Steele, M.D., F.R.C.P. *Ibid.*

Arbeiten aus dem pharmatologischen Institut der Universität Breslau, Silbermann. Archiv für Pathologische Anatomie und für Klinische Medicin, 1 August, 1889.

Cancer among females, the infrequency of. Haviland. The Lancet, September 14, 1889.

Chemische und Klinische Untersuchungen über salicylsaueres Quecksilber, Coldwell. Deutsche Medizinal-Zeitung, 9 September, 1889.

Cure of the morphine habit (translation), by Constantine Schmidt, Wiesbaden. Notes on New Remedies, September, 1889.

Der Weigert'sche Heisslup-Inhalations Apparat, Mepter. *Ibid.*

Die physiologischen Wirkungen des Palaxanthine, Salomon. *Ibid.*

Address.

INTRODUCTORY ADDRESS.

(Delivered at the opening of the Winter Session of the Medico-Chirurgical College of Philadelphia, September 30, 1889.)

BY J. M. ANDERS, M.D.,

Professor of Hygiene and Clinical Professor of Children's Diseases.

AT the outset I acknowledge that I have little inclination to say anything in defence of introductory discourses as a class. The student of the present day has, however, cause for exultation, since the time was when to every branch of the medical curriculum was devoted a preliminary lecture, on as many separate days, by as many different professors, thus encroaching upon the student's time without bringing him adequate return. Unfortunately, there are certain tutors who still introduce their annual course of lectures by one or more able efforts, dealing in grave, though usually vague, generalities, often abounding in rhetorical flourish, but containing the merest allusions to the subjects which they are expected to teach. Many of these opening harangues have been religiously preserved by their authors—not a few for several decades—and, strange to relate, without having undergone any marked changes, either as the result of atmospheric influences or the steady march of scientific advancement. My friends, should not the scientific enlightenment of the present age enable tutors to comprehend fully that all prefatory discourses are not only unnecessary but actually unjust toward the student? Should not the moral rights of the student be respected, and every obligation of good faith on the part of every professoriate be to him assured? We also front the unquestionable fact that the vocation of the teacher is to teach—not merely to theorize or speculate. To serve nobly and faithfully as the friend and educator of the student, the constant effort and aspiration of each professor must be to impart, without delay, knowledge pertaining *strictly* to his own domain. The objections, then, that can be urged against the method of introducing the student to the separate subjects of an extended curriculum by one or more irrelevant lectures are not "merely ideal," since it truly robs the student of valuable time—an affront of such magnitude as to demand that summary justice be inflicted upon all offenders. To give himself to the work of teaching with scrupulous energy, is the duty of every professor.

But whether we regard this method of introducing individual branches as criminal or useless merely, meetings such as the present one cannot fail to fill the minds of thoughtful persons with interesting reflections. Indeed, students and teachers should be alike appreciative and grateful to the men who inaugurated this custom, which is capable of yielding satisfaction to all participants save, perhaps, the man who is delivering the introductory address. In the exercise of one duty, however, I have great pleasure, namely, in welcoming you all to this comparatively new, though now well-established, seat of medical teaching. Some of you may have come from distant homes, but whether you have been contributed by States of the North, the Atlantic, Pacific, or the Gulf, or even by other lands than ours, to each one of you I bid thrice welcome.

"To thee and to thy company, I bid
A hearty welcome."

My colleagues of the Faculty will also be glad to

renew those pleasant relations that formerly existed between themselves and the classes of '88 and '89, as well as to receive and welcome most cordially all newcomers. Moreover, every member of this Faculty will, I doubt not, deem it a privilege to assist you, upon request, by their advice and counsel; and if I can to-day, by any precepts that I may utter, send you away better prepared to take up the work that lies before you, I shall be simply satisfying your just claims upon me.

We stand to-day at the entrance to another session, whose scenes and experiences you cannot divine, nor can I—though I have long since faced the ordeal—pass them in review for your benefit. I trust, however, that I may be able to lay down certain guiding principles, that will aid you in winning the battle; may tell you something that will serve "to keep hope alive to the end" of your college days. That you should at the outset expect help and counsel from your Faculty appears to me but natural. On the other hand, it should be borne in mind that, "he who will not be counselled, cannot be helped."

In our relation to you as teachers we do not assume the right of questioning the use you make of your time and talents, so long as you are prepared to meet your various examinations; but there are two leading factors to be borne steadily in mind, if you would be reasonably sure of obtaining the much coveted sheepskin, namely, the observance of right habits of study and the proper care of the body. At the beginning of his course, the student should make a resolute effort to pursue a regular method of study during his college years. To the student at the present day time is indeed precious; and he should strive to utilize, for some good and wholesome purpose, every moment. According to high sanitary authority, of the whole twenty-four hours eight should be devoted to active work, eight to sleep, and the remainder to diversion and healthful exercise. The curriculum demands from six to eight hours of your time daily; and this it is expected you will supplement by reading of text-books, recitations, etc.; hence, it will be necessary, to meet the claims of your studies, to give a considerable portion of the time normally assigned to diversion of each day to the performance of your arduous labors. For, bear in mind that you should not attempt to get along on less sleep than an average of eight hours daily. During your busy college days, then, you will apply ten hours to toil, eight hours to sleep, and the remaining six to physical needs. I desire to lay especial emphasis upon the fact that no medical student can afford to be systematically neglectful of the ordinary essentials of sound bodily health. The brightest students, the young men who give every promise of being one day the prop and mainstay of our glorious profession, too frequently fall by the wayside in consequence of their failure to pay adequate attention to the requirements of the body. I have neither the time nor the inclination to discuss the question of overwork, with its pernicious influences upon human health; but I desire to impress upon your minds this double fact: the importance of setting apart not less than four hours of each day, to be exclusively devoted to mental relaxation and physical exercise, and the importance of an abiding faith on your part in the value of muscular exercise, which faith will make that diversion pleasant rather than irksome. In general, daily recreation must be adapted to the occupation one is following. The medical student requires, first and foremost, muscular exercise; one-half hour daily for gymnastics and one hour for a constitutional walk should be the invariable rule. Should the daily walk at times prove too humdrum, this hour may be spent in some one of the more active sports. Thus, by exercising the muscular system, the nervous system will get that refreshment which, I contend, is indispensably necessary. You will also find mental diversion in the reading of light literature, and in social intercourse, which, however, should be carefully limited. Speaking of the effects of healthy recreation, a high authority tells us, "It renovates the exhausted energies, and fits them to resume their work in the most appropriate way and with the least expenditure of time." But though you will be living at a speed mentally that you cannot maintain without risk of impairing seriously physical health, unless you relieve mental tension, in the manner already indicated, I do not wish to be understood as favoring, in the slightest degree, anything which savors of the useless expenditure of time, of dissipation, or, above all, of immorality. Says Boyle: "Self-denial is a sort of holy association with God." Let this solemn truth be constantly kept before your eyes, so that none of you may fall a prey to those alluring forces which deprave character and frequently cause loathsome physical disease. Gentlemen, it is essential, in order to attain the highest degree of success, that a physician's life and conversation should conform to the moral law, and to this end it is equally necessary that the foundation walls of the moral side of his nature be laid in his college years.

In view of the fact that the field of medical knowledge is rapidly widening its border lines, and with a view to lessening the nervous tension to which the student of to-day is subjected, I would advise as many of you as may feel enabled to do so to adopt the graded four-session course. While this plan is recommended in the last catalogue, I trust that the authorities of the Medico-Chirurgical College will never rest satisfied until a graded four-year curriculum will have been made obligatory. This step would, I confidently believe, be one of those determining factors that would greatly strengthen the reputation and the status of any medical college. The Harvard Medical School is the only one that requires a graded four-year course for graduation; but the authorities who will found an additional institution of this character will accomplish much in the direction of promoting higher medical education. Since, as before intimated, the field of medical science is remarkably extensive, it behooves teachers to caution students at the outset against pursuing any single branch of study, to which their fancy may lead them, to the neglect of some or all of the rest. For, should you become never so well versed in any particular branch alone, you would not make successful practitioners, or even successful specialists. Not a few of the affections

met with by the specialist are merely the local manifestations of a general disorder; hence, in order to connect cause and effect, in every instance, as wide a knowledge as possible of general medicine is obviously essential. You shall be spared a long discourse on the subject of specialism; but I cannot dismiss the theme without advising against drifting into a specialty immediately after graduation—a course that inevitably leads to a condition of wretched narrow-mindedness. This is unfortunately the most marked tendency as well as the greatest evil of modern specialism. I plead for specialists; but from college to the position of the intrenched specialist should be a long step forward, and to gain it should demand close application to the study of general medicine, more particularly general pathology, hygiene, and general therapeutics. He should then use this general knowledge in the examination and treatment of his patients. All this is to be regarded as the essential preliminary training of the specialist. Additionally, he must receive special drilling in the particular domain which he adopts. If added testimony were needed to establish the fact that specialists are a necessity in our day and generation, we might refer, did time permit, to the more favorable results obtained by their treatment of disease both in hospital and private practice. A final point to be made in this connection is, that no physician engaged in general practice can keep up with the progress made in the various special departments of medicine and surgery.

As you approach the end of the session, you are likely to become the victims of a strange endemic affection. The most distinctively peculiar features of this complaint are, that it affects students who expect soon to be examined, and secondly, it attains its fullest development and greatest prevalence on the first day of the final examination. I have elsewhere given the following brief account of it, based on personal experience. The complaint is characterized by great pallor of countenance, palpitation of the heart, loss of appetite, disturbed sleep, increased flow of urine, and a state of the nervous system which might be called *quaky*. In no instance has the affection proved fatal, though during the attack the most awful forebodings are constant concomitants. The method of termination of the cases, seen during the endemic before alluded to, was as curious as it was variable, in that, after the terrible ordeal was past, those who were not invited to a seat in the "bus" immediately recovered; while those who were favored by a summons to the time-honored "shay" at once developed a relapse.

In this connection I desire to caution you against the practice that has from time immemorial prevailed among students preparing for examination, to wit: using tea and coffee in excess with a view to obtaining their physiological effects, which are wakefulness and stimulation of the mental faculties. In the vast majority of instances in which this custom has been followed it has led to bitter disappointment; and in a few cases that have come under my own observation to actual physical bankruptcy.

To all of my hearers who have decided to read medicine and practise the healing art, I would state, you have made choice of a high and noble calling, and one that you will not wish to change for another, more particularly after you shall have distinguished yourselves as able practitioners—not as would-be, scientific confectioners.

Bear in mind, if you please, that a three years' graded curriculum, with many prizes and honors to compete for, makes it possible for you to become, before you enter the portals of the medical profession, the recipients of quite honorable distinctions, which will in reality prove to be no mean aids when making subsequent efforts to advance yourselves to positions of prominence in the profession. Aim then at distinction. It sometimes happens, I grant you, that a laudable ambition is crossed by disappointments, but nothing can prevent ultimate victory if you will persistently aim your purposes in the direction of any high mark. Your three, brief college years are a more important and interesting epoch in your lives than may at first sight appear. The vast majority of the men of science and of note in medicine, first felt the influence of the spirit of diligent observation and investigation during college life. And in that same period was already established the habit of study and experimental research that, by and by, "makes the most difficult things easy." The tendency to make original observations with ardor is steadily increasing among the younger race of physicians—a natural corollary when we remember how much more favorable to this line of work are the advantages and facilities offered by our colleges at the present day than formerly, in the direction of improved practical and experimental methods. The encouragement and sympathy that you will receive at the hands of your tutors and laboratory instructors will, I trust, furnish the needful stimulus to further and continued scientific investigation after graduation. It may not be without interest to you to learn that, to the sum total of progress made in the last two decades in the discovery of new truths, as bearing upon medicine, the original work of the undergraduate has furnished no widow's mite. I shall not, however, discuss further the rapid advances that have been, in recent years, and still are being, made in rational medicine, since you will learn much on this head from your college studies. But I shall dwell for a few brief moments on the reforms in the methods of medical instruction that have in recent times been brought about; and more particularly to attempt to indicate what further reforms would be most desirable.

I shall ask you to use your fancy and go back with me to my own student days, commencing with the session of 1875–76, while I relate briefly something about the status of medical teaching of that time. No graded curriculum was then obligatory. The student was engaged in the task of storing his memory with facts upon facts to the utter neglect of principles. Almost exclusively, the teaching was didactic. There was a well-equipped chemical laboratory in the school; but a course of training therein meant a considerable outlay, besides, the course was not obligatory. The institution also afforded a pathological laboratory, in which normal and pathological histology were super-

ficially taught, for an extra fee; but this course was also not compulsory. On the other hand, a pharmaceutical laboratory was a thing unheard of. Again, under the old system of instruction, the student had but a single examination for which to prepare; and a knowledge of this fact led many to "waste the idle hours" during the first session. During the last year, however, and more particularly the latter half of this course, they began to be anxious and like

> Old Daddy Long-legs, couldn't say his grammar,
> Put him to the tread-mill, then to the crammer,

they, too, went in quest of crammers, on whom they relied to prepare them for the final examination. The better class of students were coached by the ubiquitous crammer from the beginning to the end of their college course. Worse than all, the student was put through the grinding process conditionally; the condition being a handsome pecuniary consideration. Hence it follows, that many students were not in a position to take advantage of the various quizzes to aid them in passing the severe trial.

There were still other defects which I will not detain you to mention, but would ask you to contrast the educational facilities of those comparatively recent times with those of the best equipped colleges of the present day. And you will agree with me when I assert that the past twelve years mark an important era in the history of medical education. But whilst we are tending toward perfection, there are still some things that need to be accomplished—some reformations to be introduced. In other words, this epoch of reform and agitation is not as yet a thing of the past.

The replacing of the ordinary quiz by recitations—a method already in vogue in a few medical schools—would be a most important improvement in medical instruction. It is universally regarded as desirable for the student to rehearse the didactic lectures, and, if this be true, to promote this end must constitute a responsibility on the part of our college authorities to the student. This granted, every professor should be held accountable for the manner in which the recitations are conducted in his own branch. With the beginning of the present session, this school has decided to adopt the plan of going over the whole ground covered by the didactic lectures, by recitations under competent instructors—a course that cannot fail of being directly helpful to every matriculate. Moreover, the step was taken entirely in the interest of the student. In a recent issue of the TIMES AND REGISTER, it was editorially advocated to substitute for the system of teaching by lectures, lessons and recitations. Whilst I am inclined to affirm superior advantages in behalf of the recitation method, I am not prepared to sanction the radical rearrangement of the present order of things, to the extent pleaded for by my colleague, the able editor of the TIMES AND REGISTER.

As before stated, the non-graded curriculum effected an overburdening of the memory, whilst at the same time the whole tendency of that system was to prevent the student from gaining a thorough acquaintance with the subjects taught. Under the most approved system of the present day, it is not so much a question of the mere memorizing of facts as formerly, but the result still is, I fear, too frequently mental overcharge, with its evil consequences, both to the mind and the body. It might pertinently be asked, What are the causes of these untoward results? To this it may be replied briefly, very largely our present modes of life and particularly the over-stimulated condition of the desires, the emotions, passions and app tites of the present race. It follows that the methods of teaching in our educational institutions need to be so modified as to favor in the highest degree the maintenance of a healthy condition of the student's mind. For, be it remembered, that an unsound mind implies impaired physical health, the one going hand in hand with the other. And this is not a question demanding the attention merely of sanitarians, but of all bodies governing schools as well.

One of the most objectionable remnants of the old system of medical education is that of preparatory pupilage, during which period the beginner usually pursued an unsystematic course of reading advanced text-books, and was brought in contact with and, observed the treatment of, the more ordinary forms of disease. Truly, this plan is practical, but fails of its object because the pupil is not prepared to appreciate what is brought to his attention. Such a course of training in practical subjects should follow some time after, rather than precede his entrance into college. And although the time spent by the student in gaining practical knowledge prior to entering upon his more elaborate studies, may not be entirely lost, it has been pertinently remarked by the British authorities, who vigorously oppose the system of preliminary pupilage, "it misleads the learner into superficiality, because it accustoms him to skim the reality of things, since knowledge and intelligence fail to enable him to reach the bottom. Moreover, the results obtained scarcely repay the sacrifice in time and trouble which they occasion the physician who acts as teacher, and still less justify the inconveniences in the treatment of disease which they bring in their train."[1]

Instead of devoting one or more years before matriculating to practical studies, for the comprehension of which he lacks scientific attainments, let the student give an equal period of time to similar work under the direct influence of an able practitioner, immediately after graduation, and the results will bear the fruit which every progressive physician desires to see ripen. The so-called resident physician in our first class hospitals, dispensaries and infirmaries, has the opportunity to gain practical knowledge and experience, which are truly invaluable; whereas, an apprenticeship in institutions such as these before entering college, would doubtless prove altogether unsatisfactory.

Within the last decade there has been started a general movement in the direction of reform in the modes of teaching hygiene. Every medical college should, to my mind, afford a chair of hygiene and a well-equipped hygienic laboratory. Every State should require those who desire to practise medicine within its borders to have passed an examination in

[1] TIMES AND REGISTER, August 31, 1889.

hygiene at one of the few medical colleges in which this branch has been made obligatory; or, in the event of not having been graduated from such an institution, to show a special certificate of fitness, obtained from the proper authorities. This qualification has already been exacted by legislative enactment in one or two of our western States. In his eloquent address before the Fortieth Annual Meeting of the American Medical Association, Sir James Grant said: "In the various medical institutions in this country, as well as in Canada, the subject of sanitary science is receiving the most careful consideration, and very justly so inasmuch as it pertains most closely to the welfare of society at large." Now, whilst we recognize the fact that many of our most illustrious medical teachers are standing at the head of the whole modern movement of preventive medicine, the truth is, that but a small proportion of the schools in America—now numbering one hundred and four—have as yet invested the subject with sufficient dignity to establish for it a full and separate chair. Of the three institutions of medical learning in Philadelphia, the Medico-Chirurgical College was the first to elevate this study to its proper rank. Let it be observed, that any school whose obligatory curriculum does not embrace a full course in sanitary science, including preventive medicine, is either not alive to the most progressive views of the profession at large, or does wilfully deal unfairly by its own graduates. Sir John Locke stated long since, that half of all human diseases were preventable; and this will be doubtless found to be true, when our knowledge of the causative agents of human ills, more particularly those that are infectious, becomes more nearly perfect. Now, I contend that it is no less a moral duty for the medical man to obviate disease, especially to prevent the spread of the infectious class, when it is possible, than it is for him to apply the means at command for the relief of existing ailments, even though it doesn't pay. Thus wrote a celebrated surgeon, of our noble profession: "We live by disease, and yet, with a genuine altruism which cannot be overpraised, we are in the fore-front of those who would destroy our means of support by pointing out the path to the preservation of health." And this is as it should be. Moreover, hygienic questions are not only of the deepest concern to the whole medical profession, but to all humanity as well; and the general public is rapidly awakening to an appreciation of this fact. Hence, every medical practitioner will, in the near future, be frequently called upon to advise in regard to, and settle, sanitary questions of the greatest moment.

One of the most welcome signs of modern medical education is seen in the inclination to elevate clinical instruction and practical technology, to a level with didactic instruction. This fact supplies the best reason for affirming that the advantages for obtaining a medical education are to-day quite as good in this country as in the older schools of continental Europe. No man is better prepared from personal observation to speak authoritatively upon this question than Dr. N. Senn, who is made to say: "There is no question in my mind, that the average American student learns more in one month than the average German student in three. He learns more not because he has better teachers or better facilities, but he makes better use of his time."[1] Surely, this is a graceful compliment to the American student.

In this connection it might be pertinent to call attention to the fact that, in comparison with the journals of European countries, those of our own land occupy a place equally high. This dictum is confirmed by my colleague, Prof. Wm. H. Pancoast, who has recently gone so far as to say that he had "much reason to praise our own journals and criticise those of foreign lands." In short, the medical literature in general of our own growing country is second to that of none other. It may not be coextensive with that of the older countries, but is certainly quite as rich in important discoveries—discoveries which have contributed so much to the cure of human diseases and the preservation of health. I shall not follow this departure from the main topic of my discourse any further, and shall therefore dismiss the subject, not however without expressing the belief that, in medical journalism, in medical literature and in the equipment of medical colleges, America will at no distant day outstrip her mother country and perhaps all other nations as well.

But though clinical instruction has come to occupy the high ground it so richly deserves in American medical institutions, this is not the case with bedside observation; which should supplement the clinic in every branch of practical medicine. In the various specialties this ward training need not be carried so far as in general medicine and surgery, in which branches a thorough course of practical instruction at the bedside, in such subjects as physical examination, symptomatology, diagnosis, treatment, surgical appliances and dressings, setting of fractures and minor operations, is needful to properly qualify the student for his life work. This bed-side training is the weakest spot in the curriculum of most medical colleges—though of prime importance—there being but a few that have made any provision of this sort whatever. It follows from all this that among the essentials of a well-equipped medical school, nothing is more important than ample clinical material.

It affords me great pleasure to say to you, that with the present session this form of practical instruction will be introduced and carried out in this school, and since the authorities believe it to be one of the requisites of a sound medical education, it shall be made as interesting and thorough as possible. Clinical as well as bed-side training should not, however, begin until the student has reached his junior year. Then, also, the junior and senior classes should be taught in sections of about twelve each. Knowledge thus gained becomes as it were, a part of the student who acquires it; and is of the sort for which one day he will have constant need. Comparatively few men have attained to proficiency as diagnosticians as the result of their own efforts.

[1] President Dawson's Address before the Fortieth Annual Meeting of the American Medical Association.

Changes in the present method of conducting the final examinations in American schools, particularly in the practical branches, is a question which seems to demand the attention of college authorities. Besides the usual written and oral examination, the student should be required, in anatomy, to present a practical dissection; in surgery, to dress a fracture or wound, give practical evidence of his ability to diagnose a tumor, or should perform a minor surgical operation; in medicine, to diagnose some disease in the living subject and outline the treatment to be given, and a similar examination should be held in the various other specialties.

My friends, if there ever was a question as to the great value to the student of laboratory work and investigation, it has certainly, during the past decade, been set at rest. Fortunately for medical science, the present race of physicians does not rest satisfied with mere assertions, but demands that these shall be backed by proof not to be doubted. Now, the various laboratories connected with our medical colleges—and there should be a well-equipped laboratory for each of the following branches, namely, pathology, histology, pharmacy, chemistry, bacteriology, hygiene, physiology, embryology and experimental therapeutics—the laboratories, I say, are the crucibles out of which are furnished the reliable data which contribute most largely to our stock of positive knowledge. All of these laboratories are to be made directly helpful to the student, by those in charge; and above all he should be allowed access to them whenever desirous of gaining information relating to special subjects. Indeed, I have a strong conviction that, in the near future not personal estimate nor personal popularity of the several members of any Faculty will be the chief criterion of a first-class medical college—though these things will always have due weight—but, rather the character and extent of the facilities offered for practical laboratory studies and clinical instruction, in connection with appropriate didactic teaching. If, as before intimated, something were done to encourage laboratory investigation among undergraduates, it would prove to be an important step in the direction of attaining to a higher medical education. Speaking with reference to the wants of our American people to-day in the line of a higher education, Bishop Potter in a recent issue of the *Forum* states: "Surely the time has come when we may ask ourselves whether enough has not been spent in planting institutions of learning, and whether something may not be devoted to enriching them. . . . . We want place for men who, whether as fellows or lecturers, shall, in connection with our universities, be free to pursue original investigation, and to give themselves to profound study, untrammeled by the petty cares, the irksome round, the small anxieties, which are sooner or later the death of aspiration and fatal obstacles to inspiration. It is with the process of thought, as it is with the process of nature—crystallization demands stillness, equanimity, repose. And so, the great truths which are to be the seed of forces, which shall new create our civilization, must have a chance first of all to reveal themselves." Truly it would be a good thing for our medical schools to establish places through liberal endowments for men who are peculiarly fitted to make the advancement of science their sole occupation. Nothing is more honorable or praiseworthy, than for a man to devote all his faculties to the acquisition of new scientific truths—"to one great and honored end"—upheld and incited by every successful experiment or bright anticipations of fresh achievements.

May it be given to some of you to pursue with single-hearted desire, a life of devotion to the undiscovered mysteries of nature, a life that should not only make you true benefactors of your kind, but the results of your labors, should one day constitute one of the chiefest glories of this, your Alma Mater.

ELECTRICITY IN SKIN AND VENEREAL DISEASES.

By JOHN V. SHOEMAKER, A.M., M.D.,
PHILADELPHIA, PA.

BECAUSE of its powerful local and systemic effects, electricity in any of its forms would be looked upon as an efficient remedy in affections of the integument, and clinical experience gives ample evidence that the assumption is true. As many skin diseases are cured by local measures, and as the application of these is not attended to by the patient with sufficient thoroughness at all times, it is evident that any agent which produces determined results under less frequent repetitions in the hands of the physician must be extremely valuable; and in such instances electro-therapy is definitely indicated.

Three forms of electric force are employed in dermatological practice—galvanism, faradism, and static induction. The latter form is first considered, as it was the earliest used in medical practice.

To obtain good results from franklinism, good mechanism must be used. The repeated failures reported by physicians in using electricity depend upon the ownership of bad apparatus and indiscriminate methods of employment; or, rather, the absence of any methodical plan of treating disease. A static electric machine to be useful must be of first class make or it won't work. The multiple plate machine of Waite & Bartlett, of New York, is well adapted to the service required, and is not, in the end, expensive, although at first sight the price may seem high.

The great objection to static electricity is its difficulty of production in hot weather; but by keeping the plates dry and free from dust no trouble need arise, and the apparatus named is constructed so as to give little labor on the part of the owner to attain good service in these respects.

In using franklinism we can employ the spark electrodes, one pole being attached to the patient by a band, or held by him, and the other applied at a little distance from the parts to be operated upon. The length and strength of the spark is determined by the distance between the sliding rods attached to

the condensers and the interval between the electrode and the person of the patient. The ball electrode, also, produces greater tension in discharge than the pointed rod, and the wooden one more than that of metal. The patient may be insulated from the ground by a proper platform and chair, in which case either simple charging, or a combined charging and spark application can be administered. Again, the person being insulated, strong peripheral effects are obtained by the use of the roller-electrode rapidly passed over the entire surface, and by powdering the body with magnesia, soap-stone, or lycopodium, the effect is intensified. Any desired medicated powder may be employed; but greasy applications are, of course, interdicted as non-conductors.

Static electricity is valuable in many nervous disorders; hence affections of the skin resulting from or accompanying such illness are often benefited by franklinism. Anæsthesia and hyperæsthesia are notably relieved by general roller electrization. Prurigo is also greatly benefited by static applications. Formication accompanying central nervous disease generally is held in abeyance by franklinic baths. As a general tonic we get splendid results in exhaustion accompanying nervous troubles, and the lividity of the skin then seen is dissipated by the acceleration of the dermic circulation under a series of short sparks. Neuralgias of the scalp and soles of the feet are sometimes benefited by franklinism after the failure of other electric treatment.

Hypertrophies of the skin, such as corns, horns, callosities, scales, cicatrices, and the like, are often removed by the thorough application of sparks, daily, over the diseased surfaces. The tendency to repeated blind boils is often aborted by strong sparks, and acne marks, hard papules, sluggish lymphatic glands, and similar disorders, are readily removed or largely benefited by drawing repeated sparks from the region affected.

In eczema and psoriasis franklinism is of much service. Where great infiltration has taken place, absorption is facilitated by franklinism, and the obstructed local circulation is relieved from pressure by the removal of poured out depositions. Much of the roughness of the skin in scrofulosis is remedied by thorough franklinism, whilst a general systemic tonic improvement accompanies the removal of the local trouble. In hyperidrosis of the feet or hands thorough franklinism is extremely valuable, as it also is in the intolerable burning and itching of those parts in persons advanced in life.

Several cases of ringworm have undoubtedly been checked in their development, and in at least two instances the painful lesion caused by the "guinea-worm" has been cured, the parasite being killed by strong and continued sparks. Sycosis is sometimes relieved by franklinism, and the "scald-head" of infants is undoubtedly benefited through continued static treatment.

The nervous twitching or spasm of the eyelids or the corners of the lips in nervous or hysterical patients usually gives way to franklinism, and the excessive flow of tears accompanying the former difficulty is frequently checked by like means.

As a general tonic to the skin, or as a counter-irritant, franklinism is equally reliable with galvanism or faradism.

Galvanism plays an important part in the treatment of many skin diseases. This form of electricity may be applied either generally—that is, the electrodes are passed over the entire surface, or centrally, when one pole is placed over the solar plexus and the other on the pneumogastric at the angle of the jaw, or, if required, it may be labile over any part chosen. Locally applied, the current is necessarily confined to single spots which require direct treatment. Galvanism is in itself a decided tonic; it is also indirectly a tonic by removing irritating or depressing disorders, and particularly so in skin diseases. It affects the nutrition of the skin, and it relieves engorgement by increasing surface circulation. Few diseases of the skin exist in which benefit is not attained by galvanism, and the main reason why more good is not secured through it is because of the indisposition of practitioners to use it, or their incredulity as to reported cures.

In chronic eczema and psoriasis no agent is of greater service than daily treatment with galvanism. The current is specially indicated where eczema is consequent on stomach or liver disorder. In these cases the central method should be used, the positive being applied to the epigastrium and the negative to the affected parts of the skin. Mild currents only are needed, twenty-five to seventy-five milliampères, particularly in females and about the face.

In erythema and erysipelas gentle galvanization will remove the stasis and reduce the swelling through the absorption of effusion beneath the cuticle. The lateral progress of erysipelas is frequently checked by galvanism applied around the affected localities, the anode being placed stabile in the center of the patch and the cathode moved slowly around its circumference. Not enough current to arouse muscular contraction beneath should be given—say from five to ten milliampères. It is to be understood, of course, that a good meter is employed in all applications; and we remark, in passing, that the full battery should be used, enough resistance being introduced by the rheostat to bring the current down to a definite strength. By this method the wear on the cells is equalized and a steady current is produced, whereas, under the use of a few cells only, constant undulation is the rule, and on sensitive points intermittent muscular contraction is apt to disturb the serenity of the patient, and by reflex trouble the operator.

Suppurative swelling of the skin or subcutaneous connective tissue, such as boils and carbuncles, may be averted, aborted, or cured by prompt galvanization in cases subject to such maladies, if the disorganization has not gone too far.

Many cases of psoriasis are due to nervous depression, and in such galvanism is efficacious, not alone from its tonic effect on the system at large, but because the constant current is of itself frequently a decided curative in this affection.

In herpes simple or herpes zoster no agent is better adapted to remove the intense burning and prostration than mild but continued galvanization. The

vesicles are rendered fewer, they are checked in their spreading, and drying is hastened by the current.

In the wretched suffering from skin poisoning after contact with the rhus toxicodendron and allied climbers, galvanism is specially efficient as a calmative and a curative.

Discolorations of the skin, such as lentigo (freckles), chloasma, vitiligo, and rosacea, are generally amenable to galvanic treatment.

In birth-marks, port-wine stain, varices, and the whole class of similar disfigurements, nothing equals galvanism, either applied by sponge-electrodes, or, when needed, by galvano puncture, in remedying the cosmetic defect.

The epilation of hirsuties, or blemishes due to abnormal development of hair, particularly on the face of ladies, is only thoroughly possible under galvanism by means of the needle operation.

In alopecia, either general or circumscribed, there is no doubt but that galvanism is unequalled as a stimulant where the hair-bulb is yet alive. Many cases of baldness which have not yielded to the whole array of hair tonics respond favorably to galvanism.

Cataphoresis, or the driving through the skin of medicinal solutions by the aid of galvanism, is likely to become valuable hereafter, though not much has as yet been done in this direction. Antiparasiticides are of greater service when thus used than when applied simply in lotions or ointments.

In obstinate gleet cures have been reported by electro-therapeutics when ordinary methods had failed. In such cases not dependent on narrowing of the canal, tender spots can be detected, and at these localities the mucous lining is more or less destroyed. In such places the stimulant effect of the current is energetic in healing the part, even when deep excavation is apparent. In the same way the local application is very useful in curing chronic ulcers of the leg, particularly when corrosive chloride is driven in under galvanism. A local galvanic couplet of zinc and silver may be worn continuously, or the ordinary application can be made by suitable electrodes and a portable battery.

The galvano-cautery is an energetic agent for the removal of warts, horns, excrescences, nævi, varices, and pedunculated marks. The heated wire has the advantage of being thoroughly aseptic, and hemorrhage is always avoided by means of electric cautery. In chancres, chancroids, anal condylomata, and enlarged glands dependent on venereal diseases, the galvano-cautery is an efficient therapeutic agent. The opening of buboes is advantageously done by the galvanic knife, and drainage is facilitated because the opening does not tend to heal so rapidly as when done by the ordinary bistoury or scalpel.

No improvement in urethral surgery excels that lately gained by the electrolysis of stricture. Under this plan any contraction can be penetrated, even when the smallest filiform instrument is needed. There is no shock, no hemorrhage, no resultant secondary inflammation, and no urethral fever attendant on urethral electrolysis. As the submucous deposit is absorbed and not merely divided laterally by the galvanic bougie, the tendency to renewed contraction does not exist; this a great advantage over forcible divulsion or cutting by concealed knives. Cases where recontraction happened after incision, have stood the test of three years without their recurrence after electrolysis. The method is applicable to stenosis of any duct or passage accessible to the proper instruments. A good galvanic battery, such as the Barrett chloride-of-silver apparatus, a milliampèremeter, and a set of bougies insulated all except the point, from No. 1 to 30, are required. Beyond the armament, practice only, or a short study of the procedure by others, is necessary.

Galvanism has occasionally proved serviceable in chromophytosis (tinea versicolor), which, though usually easily managed, is sometimes stubborn.

Urticaria, or nettle-rash, is sometimes exceedingly troublesome to many persons from the irresistible desire to scratch, which only makes the trouble worse. Galvanism will always allay the itching, and in many cases the disorder is notably shortened in duration.

Considerable attention has of late been given to the assertion that cancer in various forms was curable by electricity. The method advocated is essentially the same as that for electrolysis of fibroids, needles being introduced at the negative and galvano-chemical caustic action established under strong currents. As yet not sufficient evidence is accumulated to render an opinion authoritative, but that destructive local action can be caused in accessible cancers by galvanism is undeniable. Whether or not a specific alterative effect is attainable is not yet determined. In lupus and lupoid ulceration the good effect of galvano-causty is undeniable; hence, there may be something valuable in the proposal to thus deal with the terrible suffering undergone in cancer where objection is made to the knife.

Hemorrhage from superficial cancer, or cancer of the womb, is checked by positive polar galvanization, as is that from varices which bleed.

Faradic electricity is often useful in the same affections for which static applications are recommended. Sometimes, although galvanism appears at first to be indicated, it fails to act as promptly as had been expected, and a preliminary treatment, once or twice repeated, stimulates the capillary circulation to increased activity, and then the full beneficial effect of the constant current is bad. In many instances the alternation of faradism with galvanism is better in its results than either form alone. Most of the diseases of the integument, in which intense itching or burning is associated, are proper cases for the use of faradic currents.

In hæmophilia and hæmatidrosis which are very difficult to control, where the bleeding surface is extensive and where internal drugs do not check the flow, great danger to life exists from exhaustion. Faradism is, in these cases, invaluable, for it at once produces contraction of the capillaries.

Chilblains are immensely troublesome when once incurred, for they affect the patient year after year, even without fresh exposure to cold or to a temperature low enough to again freeze the part. Nothing is more serviceable than faradism in such cases, for it

not only removes the burning at the time of recurrence, but it breaks up the tendency to return.

In acne faradism sometimes quickly relieves the lesions and reduces the swelling of the skin. As most cases are due to stomach disorder at any rate, the central method in conjunction with localized applications is specially indicated. It is immaterial, of course, which pole is applied to the solar plexus, as the current is a reversion one, and the lettering of the binding-posts is more ornamental than useful.

In all applications of electricity to the skin, gentleness is indispensable. In galvanization particularly, every care must be taken to avoid interruptions of the current. All electrodes should be thoroughly washed after each time they are used, with boiling water. Next they should be washed with an antiseptic fluid, boric acid, or weak solutions of corrosive chloride of mercury being preferable. Always remember that many skin diseases are largely contagious, and dirty electrodes may in careless hands be the means of conveying a disease to a patient which he had not before he consulted the dermatologist, and which he never intended or expected to get in that way. In syphilitic disorders, particularly, the greatest care must be used, and it is better to employ covers on the electrodes, which can be thrown into the fire at once after using. The same precaution must be taken in applying cataphoresis—put on clean covers every time.

See that the battery, the coil, or the static machine is in good order for work every day before office hours; remember that the intensity for one patient will not agree with all; and be specially careful with ladies and children not to alarm them, for when this is once done they may be long in forgetting it.

A NEW ANO-RECTAL SPECULUM.

By ROBERT W. MARTIN, M.D.,
PHILADELPHIA.

IT would seem to be the fashion for physicians of the present day, who are led to take up a specialty in medical or surgical practice, to exploit a new system and, generally, a new instrument, designed to overcome difficulties that beset other specialists in the same fields of operation.

This is particularly the case with the specialist in rectal surgery, so much so, indeed, that the last twelve years have witnessed the birth of at least a dozen so-called "systems" of rectal surgery, each one better than any preceding system, and the exploitation of more than that number of new specula, each designed to overcome the difficulties encountered in the use of every other speculum, and, I might add, each one more disappointing than its immediate predecessor.

It is not, however, with systems the writer proposes to deal at this time, but with the more modest subject of the speculum. He has waited many years for the superior mechanical skill of other physicians in the same field of practice to develop something in the shape of a speculum that would fulfil a tithe of the requirements of a good working instrument, or that would give even a modicum of the benefits promised by each new claimant for favor—and waited in vain.

The best that can be said for any of the various forms of anal and rectal specula is not very much in the way of commendation. The *tubular* specula are difficult to introduce, and give no adequate result in the extent of surface brought into view, the field being necessarily limited by the more or less contracted inner opening.

The *fenestrated tubular* form, with closed inner end, is open to the further objection that the soft tissues, crowding into the fenestra, are likely to be torn or bruised when the instrument is withdrawn. To any one who has attempted to use one of these horrors this defect needs not be pointed out.

Those new-fangled *more or less tubular* or *conical specula*, provided with *lateral slides*, are theoretically perfect for the practitioner with only a theoretical knowledge of the use of the speculum. Their limitations are quickly discovered by a little effort to apply them to practice.

The simple *bivalve*, made upon the principle of the vaginal bivalve, is a disappointment, ever, and an illustration of the poor results usually attained by applying like mechanical methods to the exploration of such dissimilar organs as the rectum and vagina.

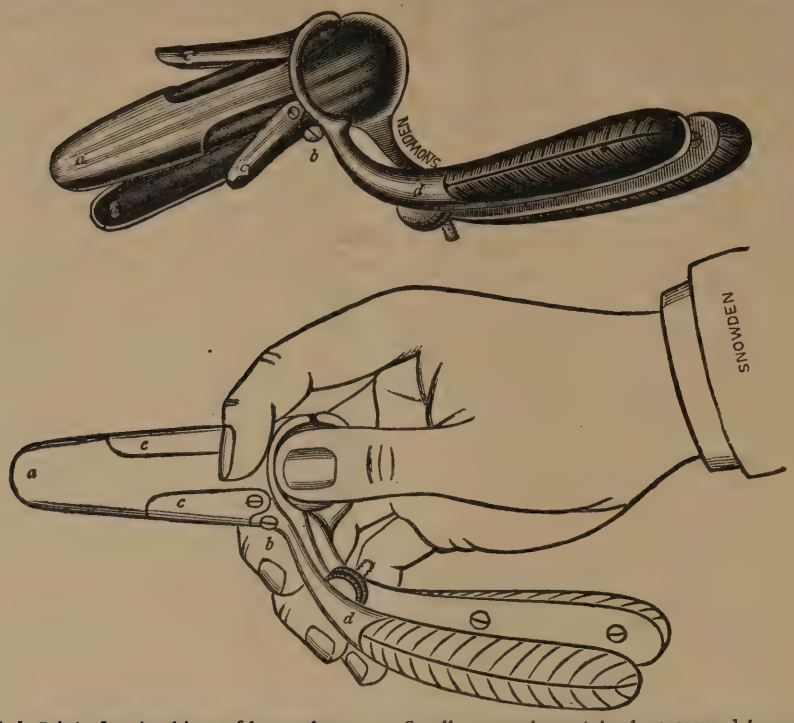
All, or nearly all, of the *contortions of bent wire* that pose as rectal specula may be classed among the puerilities of the profession—they are so manifestly inefficient; this may likewise fairly be said of the combinations of a modified Sims' vaginal and bent wire retractors or loops, with the additional adverse criticism that they cause much pain in the using.

At least two forms of *trivalve* bid loudly for favor, and they would seem to be more or less useful in a limited number of cases—*e. g.*, when there is some degree of laxity of the sphincter ani with such disease of the rectal mucosa as to render ocular inspection necessary; but it is extremely doubtful if even these conditions could not be as well, or better, met by a simple form of speculum.

The redundance of the anal folds and the laxity of the walls of the rectum require two opposing forces combined in the same instrument—viz., the distending power of the bivalve, and the restraining power of the cylindrical speculum, upon the encroachment of the intra-anal folds upon the exterior opening of the instrument.

The writer has spent many years—that is, the small amount of leisure that has fallen to his share during many years—in devising and perfecting an ano-rectal speculum combining the desirable features of the different forms of instruments in use, with as few of their respective defects, disadvantages, and limitations as possible, with this result. (See cuts, p. 538.)

The instrument is practically a bivalve speculum, giving the needed power of distension of the lower part of the rectal pouch, fitted with two very much shorter supplementary valves, which act effectively as retainers of the intra-anal folds, and prevent the rectal growths and folds from crowding into and blocking up the outer opening, thus giving a clear field of vision, and exposing the largest possible surface to view.



a. a. Long valves. *b, b.* Joint; forming hinge of long valves. *c, c.* Small or supplemental valves, secured by a pin on one side, and a screw on the other, of the base of each valve. *d, d.* Guide-and-locking arm, fitted with two milled nuts as described in the text.

FIG. 1.—Solid perspective; showing construction and appearance when open.

FIG. 2.—Outline perspective; showing appearance when closed and the ordinary manner of holding the instrument while introducing it. The letters refer to both figures.

The simplicity of construction of this instrument is such that no actuating device is necessary for the short valves, they being so arranged as to open freely by the action of the longer valves.

In practice, the writer rarely uses a self-retaining device, but frequently needs a check to the handles to prevent too wide a separation of the ends of the valves. To provide for this need, the guide-and-locking arm is fitted with a flat milled nut between the handles.

A similar nut on the free end of the guide-and-locking arm provides an efficient means of locking the handles after the introduction, thus securing perfect self-retention, and permitting the use of both hands when necessary.

The writer believes that he has introduced to the profession in this article an entirely new speculum, and one that will give general satisfaction to both patient and physician. He has in view several modifications adapted to special uses. The manner in which Mr. Snowden has produced the finished instrument from the patterns is highly creditable to his mechanical skill, and leaves nothing to be desired.

BRONCHIAL ASTHMA.—

℞.—Oxalic acid . . . . . ℥ss.
Syrup of orange-peel . . . ℥ij.
Infusion of tea . . . . . ℥vj.
M.—Tablespoonful every hour until relief is obtained.

The Polyclinic.

ROOSEVELT HOSPITAL, NEW YORK.

HYDRARTHROSIS OF THE KNEE-JOINT—INCISION, DRAINAGE, AND PLASTER-OF-PARIS DRESSING.

THIS man, aged thirty-four, has for a number of years had this swelling of the joint, which at present incapacitates him from work. He has been under treatment in Bellevue Hospital for chronic articular rheumatism. The question before us is of the nature of the swelling. The various forms of joint disease, tuberculosis, synovitis, gonorrhœal or articular rheumatism, are to be differentiated. The patient admits having had a soft chancre some years ago, but denies gonorrhœa or syphilitic infection. We can find no traces of either disease. Tuberculosis, I think, can be excluded, as the joint presents none of the appearances so characteristic of the so-called "white swelling." There is no pain on pressing the bones together, or on pressure over the joint. We have, therefore, a simple collection of fluid in the joint, the result of chronic articular rheumatism.

We shall open the joint on its internal aspect, let out the fluid, irrigate the joint cavity with a 1–40 solution of carbolic acid; insert a drainage-tube. Then the leg will be placed in a plaster-of-Paris splint.

The immovable dressing will be kept on for a week or ten days, at the end of which time the drainage-tube will be removed.

Under the strictest antisepsis there should be no suppuration.

INTERNAL AND PERINEAL URETHROTOMY FOR STRICTURED URETHRA. SECOND OPERATION ON THE SAME PATIENT.

This case is of more than usual interest, from the

fact that it is the second time the patient undergoes these operations. It emphasizes strongly the importance of after-treatment.

He was operated on a year or so ago, by the internal and external method; the caliber of the urethra restored to 31 F. Owing to his neglect in not reporting for the passage of sounds after leaving the hospital, the strictures have recontracted, and now only admit the passage of a filiform bougie.

On passing bulbous bougies, we find there is a slight contraction at the meatus, which we divide. In the anterior part of the urethra are several strictures, but here, at a distance of four and a half inches, the bougie is arrested. We try the smaller sizes, but with the same result. The guide of the Maisonneuve's urethrotome is introduced, and with difficulty passed into the bladder. The Maisonneuve tube is now attached to the guide and introduced through the stricture, the blade is rapidly pushed down and the stricture cut. Withdrawing this instrument, we introduce an Otis dilating urethrotome, dilate the canal up to 35 F.; recut to insure a perfect division of the stricture, which is hard and nearly an inch long. A staff is now passed into the bladder, and the perineal incision made in the line of the former operation; a drainage-tube will be inserted into the bladder.

The after-treatment will consist in the passage of sounds, keeping the canal patent to a 30 F. sound.

OSTEOTOMY FOR GENU VALGUM, WITH OSTEOCLASIS FOR INCURVATION OF THE TIBIA.

The cause of the deformity in this little negro boy can be seen at a glance—rickets. He is a typical example of the bone changes of this disease.

The large, square forehead, with its small, undersized face, the pigeon breast, at once attract attention and diagnose the case.

In the operation we shall do, the leg is flexed on the thigh; the thigh rotated outwards rests securely on a sand pillow. The incision is made along the ridge running from the tubercle for the attachment of the adductor magnus to the linea aspera, and in one cut is made down to the bone. The chisel is then passed alongside of the knife, and when in contact with the bone is turned at a right angle to the line of incision. As we drive it in it is inclined outward and forward to avoid the vessels. Having nearly chiseled through the bone, we withdraw the instrument and complete the operation by fracturing the leg with the hands. The line of incision is then closed with a continuous suture. We repeat the operation on the other leg.

On this side, however, beside the deformity at the knee, we have a marked incurvation of the tibia, so that we should have a poor result from our osteotomy if we did not correct this curvature, which we do by placing the leg in this instrument, the osteoclast, fixing the upper and lower third of the bone. By pressure on the middle third we cause a simple fracture.

The dressing is a plaster pair of trousers, so that the lower extremities are completely immovable from the hips down.—*Frank Hartley, M.D.*

MT. SINAI HOSPITAL, NEW YORK.

LAPAROTOMY FOR DERMOID CYST OF LEFT OVARY.

THIS woman has an abdominal tumor a little larger than a cocoanut. From its character, as ascertained by the bimanual examination, I should judge it to be a dermoid cyst of the left ovary.

The general condition of this case is unsatisfactory, and, contrary to my usual custom, ether is the anæsthetic. For the past few years I have generally used chloroform, and have had no ill results.

The abdominal walls are divided through the linea alba by a small incision, the supra-peritoneal fat picked up and divided between a pair of thumb forceps down to the peritoneum, which is lifted up away from the intestines, nicked, and the finger passed into the cavity.

By the intra-peritoneal examination of the tumor our diagnosis of its origin from the left ovary is confirmed.

A few adhesions to the intestines have formed, and, separated by the finger, a trocar is passed into the tumor, in order to evacuate its contents so as to have it pass through without enlarging the incision. The thick, fatty-like material which flows so slowly through the canula again sustains our opinion as to its dermoid character. Having extracted the tumor through the wound, we will now proceed to ligature the pedicle. For this purpose I always use the Staffordshire knot, introduced to the profession by Mr. Lawson Tait. This knot, as you will see, ties the pedicle in two halves, then binds the two halves together. After making this knot, I take another turn with the free ends, and tie them with a surgeon's knot. This second turn is merely a matter of habit. Now that the pedicle is tied off, we will remove the tumor, and I do this by searing through the pedicle above the ligature with the Paquelin cautery at red heat.

THE "TOILETTE" OF THE PERITONEUM.

This term, introduced by Dr. Keith, of Edinburgh, is applied to one of the most essential points in abdominal section, *i. e.*, a thorough cleansing of the peritoneal cavity, which we will now do. A sponge is pushed deep down into the pelvis, and, as you see, is wet with bloody serum; another is introduced and again wetted. As there is only one place where oozing can take place, the point where the adhesions were separated, we will examine them. There is only one oozing point which we will tie off with catgut; then, again placing our sponge in the pelvis, it returns dry and clean, so that we can close the peritoneal cavity, confident in its cleanliness.

For closing the abdominal wound I have for some time past used silkworm gut, but having had in several cases stitch wound abscesses, I will use twisted silk with superficial catgut sutures.

The dressing consists of iodoform gauzes covered with rubber tissue, and a snugly applied binder. The bowels will be moved on the second or third day by small doses, frequently repeated, of some saline laxative; or, if there should be much flatus, by a turpentine and castor oil enema.

The cyst contains fatty material with a large ball of dark hair. No plates of bone can be found.

SEMMOLA ON HYDROTHERAPY.

ANY contribution to therapeutics by the eminent professor of Naples, must receive respectful consideration, because in him are happily blended the physiologist, the philosopher and the clinician. A series of papers published in the late issues of the *Internationale klinische Rundschau*, on The Modern Strivings of Therapeutics, present the views of this eminent teacher in such a clear and philosophic manner, that it has become the subject of numerous editorial comments in our journals. Semmola's views on hydrotherapeutics, a subject to which, as our readers are aware, we are devoting much attention, are so fully in accord with our own, as expressed in an issue of July 27, 1889, that we quote them here in extenso :

"The principle upon which, for so many years, rational therapeutics was based, was a belief that we could apply to diseased conditions those biological effects which have been recognized in the healthy state, and which were expected to produce the same effects when put into antagonism to the disease. This is a principle, in contradiction to the laws of the experimental method, which teaches that when the conditions of the phenomena are different it is impossible to repeat the same experiment with the same effect. Natural therapeutics, on the contrary, which is capable of curing, by obedience to physiological laws, the most severe temporary pathological processes, which emanate from the prolonged effect of ordinary external causes, offers the physician always the best aid and surest support, even in the most difficult and desperate cases. I select as an example of the diseases to which I have referred already, the rheumatic diathesis and herpetism.

In visceral diseases, which defy all treatment so long as they are favored by the existence of these peculiar alterations in tissue change (rheumatism, etc.), the physician may, in many cases, attain a true and real cure, by endowing all the functions of the organism with the highest activity, without the addition of medicinal substances—*i. e.*, the heterologous modifiers ; but singly and alone by the application of the ordinary physiological agents, *the chief of which is hydrotherapy*. The methodical, internal as well as external use of water, graduated in temperature according to the indication ; climate, proper alimentation, muscular exercise, etc., are aids by which hydrotherapeutics excites skin activity and with it all the function of tissue change and organic degeneration, so that often real marvels of recovery in severe and desperate cases are accomplished. Unfortunately, these marvelous results are far more rare than those obtained hitherto by Priessnitz, and *of which I was myself a witness*. The reason of these diminished successes, appears to-day to lie in the fact that hydrotherapeutics has become a monopoly of exclusively trade physicians, who treat various diseases without careful adaptation of the hydriatic procedures, and receive patients even for two or three weeks ; only, of course, there are to-day celebrated exceptions, as, for instance, Winternitz, in Vienna, and Benobarde, in Paris, and others. But, unfortunately, the competition is too severe.

Without entering here into the mechanism by which an intelligent and earnestly executed hydrotherapy may lead to a rapid organic renewal, provided that the organs of life can bear this newly imposed activity, one thing is certain that this organic renewal can only be attained by physical agents—*i. e.*, by means acting like the normal functions, which are increased only gradually.

It is to be regretted that physicians in general do not accord to hydriatic treatment the value to which it is entitled. And still hydrotherapy represents in an entire series of affections, especially those in which the tissue changes are involved, *the only effective, rational etiological treatment.*" (Italics are the author's.)

In the article referred to in our issue of July 27, we took occasion to quote the language of one of Germany's most noted clinicians, Prof. von Ziemmsen, who writes in almost the same strain.

The testimony of two men, whose renown as scientific observers and clinical teachers is world-wide, will, we trust, enhance the interest in hydrotherapeutics, with which we endeavor to invest it by devoting a department in our columns to the subject. In making this new departure we are guided solely by a desire to afford our readers all the aid in their battle with disease, that may be gathered from the most fruitful and trustworthy sources.

IN the department of dietetics no subject occupies the attention of the medical world at present of such importance as that of the transmission of tuberculosis through the food. In another column will be found a report of the discussions at the French

Academy. It is evident that the recommendations of the Committee went farther than is warranted by the facts of the case, as yet demonstrated. Nobody is found to doubt the contagion of the disease. The principal source is undoubtedly the dried sputa of consumptives, and all agree as to the necessity of avoiding this danger, by compelling patients to use proper vessels to receive, and destroy the noxious qualities of, the sputa. While the transmission of tubercle by meat and milk is less clearly demonstrated, and either denied altogether or limited to exceptional conditions by Seè and others, it must be borne in mind that negative evidence in such matters weighs but little against positive instances. The occurrence of a single case of such contagion is sufficient to establish the reality of the danger, even were one hundred cases to be cited where the use of the tuberculous food failed to induce the disease. To what degree this danger really extends, and what conditions favor or prevent it, remain to be shown; and this is the task of the Committee to which the Academy has referred the question.

It is certain, however, that in recommending that all animal food, even of healthy beasts, should be subjected to thorough cooking, the Committee went too far. This would shut off from our tables the "rare beef," which has been universally found most palatable and digestible for the sick and the well alike. It were better to provide for the efficient inspection of all such products and forbidding the sale of the flesh of tuberculous animals or of their milk. The prompt slaughtering and burning the bodies of tuberculous animals would be a most salutary measure in many ways. It would prevent the use of infected products, limit the spread of tuberculosis among cattle, and improve the condition of the latter by compelling the farmer to keep his stables, etc., in a hygienic condition. This would in every way be preferable to the indiscriminate condemnation of rare meats.

M. Lancereaux sought to bring back the attention of the Academy to the other half of the question; that of the predisposition to phthisis. This was a mistake. Nobody can define exactly wherein this predisposition exists; as anything which tends to debilitate favors the operations of the bacillus; while the fact that about one-fifth of the human race dies of tuberculosis shows that the liability to its attacks is practically universal. Given, a tuberculous wife, sleeping with her husband and expectorating tubercular sputa all over the carpet of their bedroom; let the latter be small, rarely aired or cleaned, and illy ventilated, and we would not insure the life of her husband, were he the most powerful man who could be picked out, to resist contagion.

Were milk so dangerous an article of diet, we should have tubercular disease of the alimentary tract much more frequently than we have, in infants raised upon cow's milk. But here we are met by another question: How do we know but that many of the intestinal diseases of infants are really due to the tubercle bacillus? Autopsies on infants are infrequent; the possibility is that acute infection of the alimentary tract by this parasite may often occur, and the resulting death be credited to cholera infantum, marasmus, or indigestion. The investigation of this class of infants' diseases offers a promising field for the bacteriologist; especially in view of the utility of intestinal antiseptics, whose use is rapidly growing in popularity, as experimentation widens the field of their utility.

MEDICAL ATHLETICS.

NOTHING will teach a student more dexterity and gentleness in passing the steel bougie than the passing of it upon himself; nothing so vivifies to his mind the effects of drugs as their occasional use upon himself. No part of a physician's advice is more important than fresh air and outdoor exercise. Athletics have become a feature in all our universities and great schools, and though in some instances they may be carried to excess, in general they are to be commended and encouraged. Because a college athlete appears to study less than the sallow-faced plodder who pores continuously over his books, it is no sign that the former is not acquiring as much knowledge as the latter. Frequently he is gaining more of it, and in such a way that he will be able to retain it longer. With plenty of congenial exercise, well regulated and in the open air, the blood is set aglow and sent coursing through the brain, starting it into a more rapid and healthful activity, so that the collegiate studies become easier and more interesting to the student. College athletics, however, may be overdone, and are then as injurious as their total neglect.

But with medical students there is a double necessity for the cultivation of athletics. They need it, in the first place, for their own health, and secondly, for the proper instruction of their future patients. It is with athletics much the same as with the preparation of foods for the sick, physicians know when and what to recommend well enough, but not the how of it. Patients are frequently met so ignorant or so dependent in their confidence of the doctor that they will ask how to prepare the simplest articles of diet, and how to take the prescribed exercise. The physician should, if possible, be prepared to meet so natural a query with his own knowledge and experience. In London athletic clubs are organized among the hospital students, and contests fought, not only between the different hospitals, but even between the different cities. Without necessarily going to this extent, all medical students should take daily, muscular exercise, something more than mere riding and walking. Regular athletic exercise should be considered as a part of the student's daily routine, and it should be made more agreeable and beneficial by occasional intercollegiate contests and competitive trials.

Annotations.

EVERY word which has been spoken or written against milk, as a vehicle for the transmission of tubercle germs, is an argument in favor of the use of condensed milk and the baby foods; in which any disease germs existing in the milk are destroyed by the heat applied to drive off the water. If these preparations are put up so as to prevent subsequent contamination, as they generally are, they are safer than milk; unless the latter is thoroughly boiled. Where we can rely on this being done, the milk is as safe as any manufactured food; even if we cannot know whether the milk is derived from a healthy animal or not. But it is well for the physician to assure himself personally that his directions are properly carried out; as domestics have a way of assenting to them and then doing as they themselves prefer. We recollect one case in which we had laid down the strictest directions as to the food of a sick child; and came in to find the nurse giving it, from a dirty cup, some milk, so sour that it had coagulated. It is never safe to presuppose the intelligence to comprehend, or the care to execute, the directions given.

THE opening addresses at the Philadelphia Colleges will be received with unusual interest this year, on account of the changes recently made in the teaching corps. The salutary influence of competition is evident. It is not sufficient for a candidate to gain the honor of a chair, but he must show his ability to fill it efficiently and acceptably. Many physicians can be found who are men of culture and of intelligence, whose knowledge of the art of healing is so profound as to win the respect of their fellows, but who yet have no ability to teach, or whose dispositions are marred by pride or bitterness to such an extent as to destroy their usefulness. One of the inevitable mistakes of the newly-inducted lecturer is the attempt to teach too much; in the fulness of his ripe scholarship forgetting that the three short years of the medical course barely suffice for the rudiments of the science. We can only lay the foundation, but this should be done in a way to render the future edifice secure, and to avoid the need of too much tearing down and rebuilding. In this connection, we recall a remark of Professor Forbes, pregnant with wisdom—that our object is not to prepare students to pass examinations, but to become practitioners. This is too often forgotten by teacher as well as pupil in these latter days of competitive examinations. The warning comes with the best grace from a professor in Jefferson College, which has, from her foundation, been distinguished by the practical nature of her instructions, and whose graduates have approved the value of her teachings by their success in the field of active practice.

THE question opened by Dr. Bidwell's paper upon "The Curse of Schools," in one of our recent numbers, will undoubtedly lead to rejoinders by those holding various opinions upon the subject of sectarianism. It may be well here to remind our readers that the TIMES AND REGISTER is not a partisan journal; that it is not an organ, save of the whole profession, and that its columns are open to all who choose to discuss the question in a proper manner, but the journal advances no opinion of its own. In fact, among our ranks it is probable that every shade of belief upon this subject may be represented. Speaking personally, we may express the hope, in common with all who care more for scientific work than polemics or politics, that the day is not far distant when there will be but one school of medicine, in which each may work in the manner which is most in accord with his own views, as deduced from his own study and observation.

Letters to the Editor.

CARE OF THE INSANE.

IN your issue of August 31, 1889, Dr. Blumer makes a correction as to your statement in your issue of August 10, quoting him in my recent papers on "Belgium and Her Insane Institutions."

Dr. Blumer's statement to me, that seventy per cent. of the inmates of his institution could be placed in detached buildings on a farm without danger of injury to themselves or others, was not in anywise connected with the Gheel plan. That was not discussed. We were discussing the use of farms and detached buildings or colonies, like the colony plan of Michigan and others.

He had not read my paper when he sent you his card. The conversation was at Albany, in the room of Senator Sloane, upon the subject of farms; and outdoor exercises and detached farm buildings, rather than large and expensive State institutions, were under discussion.

In my article referring to New York, with her large institutions at Utica, Auburn, Middletown, Willard, Binghamton and Buffalo, and the project of building a large asylum in the North, I asked this question:

"Why should we not consider how many of our insane could be transferred into families upon farms, where they can have out-door exercise, labor and occupation combined with it?" citing the Neast law of Massachusetts, where such experiments were authorized under proper medical supervision, and I insisting upon careful medical supervision as a *sine qua non*.

Dr. Blumer's statement to me would, I think, be concurred in by a majority of American superintendents.

And I am one of those who would be glad now if half the money lavished on munificent structures for the insane could have been invested under such judicious and more beneficial methods as the recent work under the charge of Dr. A. E. MacDonald for the city and county of New York, on what we call the Long Island farm. CLARK BELL.

DIPHTHERIA is epidemic in the lower end of Berks County.

CASE OF PRECOCIOUS MENSTRUATION.

ON August 14, a negro, named Cobb, called on me and stated that he had a daughter, not quite four years old, who had been menstruating for over two years. The child was born in October, 1885, and in July, 1887, its mother noticed a slight discharge from its vagina. She took the child to Dr. Westbrook, who prescribed, and in a few days the trouble passed away. Again came the discharge and again the doctor cured it, but it wouldn't stay cured, so it dawned on my friend's perceptions that the attacks and cures were periodical, and he so informed the parents. In a short time it became a regular menstrual discharge, normal as to time, quantity, and material. On my request the child was brought before our County Medical Society at its late meeting.

We found her a well-grown negro child, very intelligent for her age, with breasts fully developed, pubes wearing the adult garb, and actually menstruating. She is the tenth child of her parents, who are each about forty-three years of age, and in good health.

As few menstruations are so previous, I place the report of this case at your service.

A. J. JAGOE, M.D.

HERNANDO, MISS.

MASSAGE OF THE UTERUS.—Dr. Norstroem advances the following rules, which are to be observed in the massage of this organ :

1. Graduate the pressure on the uterine body after you have seized it.

2. In order to get a good hold, push down during expiration; maintain the distance gained during inspiration, and start again during the next expiration.

3. Be careful not to increase, by any sudden movements, the painful impression experienced by the patient when the uterus is first taken hold of; wait a moment before beginning pressure. The pressure sometimes produces reflex pains in various parts of the body.

4. Devote all your attention to support the uterus; this is easy when it is large and soft; very difficult when it is small and hard; it is then that it moves with great facility to one side or the other.

—*Gazette de Gynécologie.*

EXPLOSIVE MEDICAMENTS.—Professor Robert calls attention to the following explosive mixtures: Chlorate of potash mixed with charcoal dentifrice powder may explode, even in the mouth. Chlorate of potash mixed with catechu, or with tannin, explodes with friction, even if glycerine is added. Chlorate of potash and phosphate of sodium explodes while mixing the powder. One part of chromic acid mixed with two parts of glycerine explodes immediately. Iodine and ammonium should never be mixed together, as it is extremely apt to explode. Bromine and alcohol, forming the bromide of ethyl, often explodes. Picric acid reduced to powder explodes, when mixed with any other substance.

Society Notes.

NEW YORK ACADEMY OF MEDICINE—SECTION ON ORTHOPÆDIC SURGERY.

Stated Meeting, April 19, 1889.

A. B. JUDSON, M.D., Chairman.

PSOAS ABSCESS FOLLOWING POTT'S DISEASE.

DR. V. P. GIBNEY presented a patient, a girl fourteen years old, on whom he had operated for double psoas abscess following Pott's disease of nine years duration. The carious vertebræ were evidently consolidated when, last November, large abscesses were discovered, and the patient was brought under treatment. On the right side, the tumor was incised in Scarpa's space, and long forceps were passed under Poupart's ligament through the iliac fossa, and into the lumbar region, and a counter-opening was made on the forceps along the border of the erector spinæ muscle. Pieces of bone escaped with the pus. The cavity was curetted, and the bone scraped gently. With antiseptic dressing and injections of carbolic acid solution 1–40, and 1 per cent. creolin solution, both wounds closed in a month. The left side was then operated on by simple incision and drainage. Large quantities of bone detritus were scooped out with the finger. A sinus still remains on the left side from which a piece of bone is occasionally discharged.

The case was exhibited as showing the advantage of Owen's method of attacking simply the sac and not the whole suppurating track.

Dr. Gibney believed it would have been better to have treated both sides according to Owen's method; but in general he doubted the propriety of doing this operation. It is also important that the patient should be in a pretty good condition.

DR. R. H. SAYRE had used injections of peroxide of hydrogen in large abscess cavities, with better results than from carbolic, or bichloride, or boro-salicylic solutions.

DR. GIBNEY said that a similar experience had been reported by Dr. Vance.

DR. JUDSON thought an objection to operating on these cases was that for the natural incarceration of the pus and detritus, we substituted an artificial opening, necessitating antisepsis to hasten cicatrization. If these accumulations are doing no harm, it is better to leave them for removal by natural processes; and if in due time they perforate the skin, the general and local conditions are ready to promote evacuation and speedy cicatrization.

DR. J. A. WYETH said that operation is indicated when large abscesses are situated in exposed parts of the body, and liable to injury and subsequent septic complications. He recalled the case of a woman who, thirteen years after being considered cured of Pott's disease, slipped and fell on a large gluteal abscess. The accident speedily gave rise to symptoms of sepsis with high febrile movements, and several operations under ether were necessary for the removal of bone detritus, which was spread through the gluteal muscles. The patient ran great risks, but finally recovered. He had had other similar cases. A psoas ab-

scess behind the peritoneum causing no trouble should be left alone, but one pointing in the thigh, back, or other exposed situation should be operated upon, as the danger of the operation is almost *nil*.

Dr. N. M. Shaffer was reminded of the history of a patient with Pott's disease and an abscess occupying the gluteal region and the anterior part of the thigh. The child fell, striking the gluteal tumor. The immediate symptoms were alarming, but without the adoption of any special treatment, the accident resulted in the entire disappearance of the abscess. If there were any means of determining with certainty when an abscess from Pott's disease contains bony detritus, it would be preferable to operate ; but while spondylitis is still active, it is better to postpone operation as long as possible.

He recalled a case of Pott's disease and hip-joint disease which he had been watching for several years, where spiculæ of bone as large as the end of the finger were expelled in a sudden and violent attack of coughing. The bone was undoubtedly from the cancellous structure of the sixth or seventh cervical vertebra. The patient was relieved at once, and physical examination showed that very little trouble had been caused by the entrance of the bone through the lung tissue into the bronchial tubes.

KNOCK-KNEE—CLUB-FOOT—DEFORMITY FOLLOWING HIP DISEASE.

In a paper on "Osteotomy," Dr. Wyeth related two cases in which he had corrected in- and out-knee in the same patient by double osteotomies. The patients were three and a half and four years old respectively. Both were discharged entirely relieved. Strict antisepsis was followed, and the limbs were dressed in plaster of Paris in a position of over-correction. He prefers MacCormac's incision on the outer side and just above the capsule, since the saphena vein and anastomatica magna artery are not endangered as in Macewen's operation on the inner aspect of the thigh. He also briefly related three cases in which patients aged thirteen, eighteen, and twenty-six years, respectively, had been relieved of the deformity following hip disease, and restored to good locomotion by operations on the femur. The method pursued was Gant's osteotomy below the lesser trochanter. The after-treatment had been Buck's extension and Hamilton's long splint. In one of the patients there had been double hip disease. Two months after the left femur had been operated on, the right was operated on ; and four months after the date of the first operation, the patient was discharged cured, with good locomotion.

He also related two cases in which congenital talipes equino-varus of the most exaggerated type had been corrected with good recovery, and with the feet in excellent shape. Tenotomy of the tendo-Achillis, tibialis anticus, and tibialis posticus was first done ; the first two subcutaneously, and the last by open incision, the tendon being disassociated from that of the flexor digitorum, and divided on an aneurism needle. The operation was completed by an osteotomy as follows : An incision was made on the outer side of the dorsum, exactly over the point of greatest convexity ; the tissues were lifted from the tarsus by an elevator, and a conical section, including portions of the calcaneus, astralagus, cuboid and scaphoid was removed. The rule should be to remove all parts which prevent replacement of the foot. The foot being brought into normal position by eversion and rotation, aseptic dressing and plaster of Paris completed the treatment, the result of which was excellent.

Dr. Gibney said that the anatomical point raised in the paper concerning supra-condyloid osteotomies certainly commends to us the operation of MacCormac. Although in- and out-knee in the same subject is rare, he had seen many instances of multiple deformity among Bohemians and Italians. He had recently done a sextuple osteotomy at one sitting, and is treating an ununited fracture of the right tibia, all the others having united.

Dr. Judson thought that in congenital talipes the reduction of the deformity by mechanical or operative means is easy ; but that is a small part of the necessary treatment. So long as the patient is growing, he must be under occasional observation, and, if necessary, made to wear, for a few months, at intervals of two or three years, a brace fitted to the present needs, in order to prevent threatened relapses. In the deformities of the knee, there is especial reason for preferring mechanical means of correction, because here we have the advantage of the leverage found in the tibia and femur ; while in club-foot there is only the tibia on one side, and on the other the short and many-jointed foot.

Dr. H. L. Taylor said that late observation of the results of treatment is of especial importance in orthopædic practice. If surgeons and orthopædists would report the condition of patients five, ten, or more years after dismissal, a more intelligent choice of methods could be made.

Dr. Shaffer said that his experience with mechanical appliances in the treatment of talipes leads him to think that many severe operations are performed on patients who could be better treated by traction. He recalled a case in which there was confirmed equino-varus, although three or four tenotomies and five or six osteotomies had been performed. He had applied the "external lateral stretcher," and the patient is now walking on the flat of the foot, He referred to the interesting question whether osteotomy is advisable when there is motion in the hip-joint. In a patient on whom Dr. W. T. Bull had operated, some motion was found after etherization. The reduction of the deformity by osteotomy had been followed by persistent traction with the hip-splint ; and good position and slight motion had both been retained.

Dr. Gibney believed that the presence of motion is not a contraindication to the operation. About six months ago, he had performed Gant's operation for a right-angled deformity. The flexion had been reduced from ninety degrees to fifteen degrees, and the limb was retained at fifteen degrees of flexion by a traction apparatus for three or four months, when it was removed and the patient allowed to walk about with a high shoe. After about six weeks the flexion

had increased to twenty-five or thirty degrees. Traction was reapplied, and the limb is being again brought down. He recognized the necessity of protective apparatus in order to retain or increase the result secured by operation.

Dr. Wyeth had operated in several cases where there was motion, and had refused to do it in others. In a patient whom he had seen with Dr. L. A. Sayre, there was considerable motion, and he had done a tenotomy for temporary relief, postponing osteotomy.

Dr. R. H. Sayre said that in the case referred to, improvement had followed the tenotomy, but an apparatus is necessary to prevent a return of deformity. He thought that in some cases sufficient reduction of the flexion might be brought about by section of the psoas and iliacus muscles. This had been done in one case in which, although the operation had been subcutaneous, injury of the vessels had been avoided. By open section this danger would be avoided.

Dr. J. D. Wilson expressed surprise at the frequent mention of elevations of temperature in the history of Dr. Wyeth's cases, which had been treated antiseptically. Have our teachings been too absolute, or do such temperatures really indicate imperfect antisepsis?

Dr. Wyeth replied that "the temperature of reaction," occasionally as high as one hundred and two degrees, occurred in the first twenty-four hours, but it usually fell to normal in forty-eight hours. Traumatism, ether, shock, and the use of sublimate combine to produce this reaction, which might still be called an aseptic temperature.

He closed the discussiou by saying that the simplicity and safety of osteotomy had been shown by the cases he had reported. While no case of equinovarus treated the first two years of life should require tarsotomy, neglected cases will present themselves where nothing but tarsotomy will give relief. The operation may give considerable foreshortening to the foot, but one can certainly correct the deformity, however great, by removing enough bone; and if this be properly done, he believed it to be real conservatism.

NEW YORK STATE MEDICAL ASSOCIATION.

THE New York State Medical Association met at the Hotel Brunswick, at 9.30, on Wednesday, the 21st inst.

The Association was called to order by Dr. W. T. Lusk, the President, and the reports of various committees and officers were read. The papers brought before the Association were:

Inversion of the Uterus, novel treatment; the Latero-dorsal Position in Gynecic Irrigation, by Dr. George E. Fell, of Erie county.

The Treatment of Uterine Fibroids by Electricity, by Dr. H. D. Ingraham, of Erie county.

Pelvic Cellulitis in Women, by Dr. N. H. Robb, of Montgomery county.

Report of a Case of Laparotomy for Ruptured Pyosalpinx; Error in Diagnosis; Recovery; by Dr. Charles S. Wood, of N. Y. county.

Committees were then appointed for nomination of officers, etc.

The afternoon session opened at 1 P. M. Dr. Lusk read an exhaustive paper on Tubal Pregnancy, in which the subject was judiciously handled, and will be published. It was discussed by Dr. Goodell, who objected to the use of electricity, and would only resort to it in the event of refusal of an operation by the patient. Electrolysis, especially, is always fatal. The success that some claim from morphine surprised him greatly.

In his opinion, laparotomy is always the best recourse, especially after rupture. He claims that there is no report of a death in Tait's experience nor in Philadelphia, unles the patient was in a dying condition.

Judging from his reading on the subject, he would prefer to leave the child until it is viable, even to the eighth month, then remove the whole sac, or remove the fœtus and sew the edge of the sac to the wound, and put in a drainage tube. The latter is not done by Tait, but he cuts the cord, squeezes the placenta, and seals the sac hermetically In a twin case, one writer had an extra uterus. Edes, of Washington, has succeeded in saving the mother by laparotomy, and delivering her at term afterward.

He would regard Porro's operation as the best in twin pregnancies. Dr. Goodell then cited a number of cases illustrating the difficulty of diagnosis and the methods of treatment, among these the case which induced Parry to write his classical work. Goodell regards incision over the tumor as far preferable to the median line, because in the latter the peritoneal cavity is opened. Recovery is usually prompt.

Dr. Marcy, of Boston, related two cases which he studied with reference to etiology. He concluded that, contrary to Tait's opinion, these were purely abnormal. One died from intestinal obstruction, and in the other the sac ruptured, and an autopsy showed that a timely laparotomy would have saved the woman. This occurred long before the operation came before the profession. Dr. Marcy is also opposed to electricity.

Dr. Janvrin, of New York, believes laparotomy is the best treatment for a recognized case prior to the fourth month. There can certainly be no doubt of the propriety of laparotomy if the sac is ruptured. The diagnosis is not difficult; he especially dwelt upon the colicky pains after the usual symptoms of pregnancy have existed, on the distinct tumor on the side of the womb, and on the very sensitive character of this tumor, and on spasmodic expulsion of more or less blood. In cases of great doubt an exploratory laparotomy is justifiable.

Dr. Lusk closed the discussion. He advocated electricity in preference to laparotomy, because any general practitioner can do the work; it is so simple, and destroys the fœtus before the third month without trouble, while a laparotomy is almost always fatal in inexperienced hands, and in the absence of skilled assistants and nurses. He does not approve of leaving the placenta and rubbing it with bichloride of iron to stop the bleeding. Meeting adjourned till 7.30 P.M.

[To be concluded next week.]

Book Reviews.

CANCER AND ITS COMPLICATIONS. By CHARLES EGERTON JENNINGS, F.R.C.S., Eng., M.S., M.B. London: Baillière, Tindall & Cox, 1889, 154 pages.

One of the most interesting problems before the surgical profession to-day, and one in which the attempts at elucidation have been both numerous and ingenious, is that occult and complicated question, the pathogenesis of carcinoma. The controversy on this subject has been one of peculiar interest, and has drawn into its vortex able men versed in polemics, who have taken their position on either side, and thence contributed their weight of testimony and ratiocination. As Dr. Moxon has tersely expressed the present state of affairs, the whole argument hinges upon the solution of the question, "Does the general condition precede and cause the local, or does the local condition precede and cause the general?" Since "statistics show that the annual mortality from cancer is increasing both actually and relatively to the population," and since the principles of a rational plan of treatment for cancer depend altogether upon the way in which we regard this question, it is patent that it is of the utmost importance that we arrive at a speedy conclusion.

The balance of evidence seems to be tending towards a local pathogenesis, and Dr. Jennings, who is recognized as a leading localist and a strong advocate of his party, has written this book mainly to confirm and elucidate his theory of the precedence of the local condition, and to urge his argument that complete extirpation of the disease in its earliest stage may be considered curative. That he has succeeded in presenting a strong and decisive case must be admitted by all who will read his book, and we would say that by his concise and masterly handling of the whole subject he has done much towards advancing the matter to a satisfactory conclusion.

SAUNDERS' QUESTION COMPENDS, No. 7. ESSENTIALS OF MATERIA MEDICA, THERAPEUTICS, AND PRESCRIPTION WRITING. Arranged in the form of Questions and Answers. Prepared especially for Students of Medicine. By HENRY MORRIS, M.D. Philadelphia: W. B. Saunders, 1889, 250 pages. Price, $1.

In no other branch of medicine has there been such progress made as of late in the department of materia medica and therapeutics. Dr. Morris, in preparing his compend, has endeavored to keep pace with these rapid strides, and with a few exceptions, notably some of the coal-tar extractives, he has succeeded in giving us a concise and yet comprehensive review of his very extensive field. In arranging his drugs for the purpose of study, he has adopted a classification based on therapeutic grounds rather than on physiological.

SAUNDERS' QUESTION COMPENDS, No. 1. ESSENTIALS OF PHYSIOLOGY. By H. A. HARE, B Sc., M.D. Second edition, thoroughly revised and enlarged. Philadelphia: W. B. Saunders, 193 pages. Price, $1.

In presenting the second edition of this valuable little compend, Dr. Hare has appropriated all of the recent advances made in the department of physiology to further amplify the usefulness of his book. Difficult points in the study of the nervous system have been elucidated, while the number of illustrations has been increased threefold. As it now appears, the compend cannot fail to merit the full appreciation of the overworked student, whose chief aim is to secure the essence of his studies condensed into the smallest bulk of readable matter.

THE MEDICAL REGISTER OF NEW YORK, NEW JERSEY, AND CONNECTICUT, FOR THE YEAR COMMENCING JUNE 1, 1889. Published under the supervision of the New York Medico-Historical Society. WILLIAM T. WHITE. M.D., Editor. Vol. XXVII. New York: G. P. Putnam's Sons, 1889,

This volume contains the names of 7203 physicians.

Pamphlets.

Responsibilities and Duties of the Medical Profession Regarding Alcoholic and Opium Inebriety. President's address before the thirty-ninth annual meeting of the Illinois State Medical Society, May 21, 1889, by Chas. Warrington Earle, M.D., Chicago.

Cephalæmatoma of the Newborn, by C. W. Earle, M.D., Chicago. Reprint from Journal of American Medical Association, 1883.

On the Healing of Aseptic Bone Cavities by Implantation of Antiseptic Decalcified Bone, by N. Senn, M.D., Ph.D. Reprint from American Journal of the Medical Sciences, September, 1889.

The Medical Digest.

MERING and Minkowski show by many experiments that extirpation of the pancreas results in true diabetes mellitus.

DORN recommends that in making rhinoscopic examinations the patient's head shall be allowed to hang back over the end of a table. This renders work easy and lessens the danger of hemorrhage.

ANEMONIN, in doses of three-quarter to one and a half grains, divided in two cachets, is recommended in whooping cough, bronchitis and asthma. It is a cerebral poison, annihilating the function of the central nervous system, when given in large doses.

—Merck's *Bulletin*.

DEATH OR ABORTION.—Gaillard's *Med. Journal* reports a case in which a woman took a drachm of oil of pennyroyal and half as much fluid extract of ergot, to induce abortion. She recovered under the use of morphine and atropine hypodermically, heat externally and free administration of milk. The fœtus was not injured; pregnancy proceeding normally thereafter.

It is a pity that women so inclined cannot be convinced that drugs will not produce abortion, except in exceptional cases, unless given in such large doses that the death of the mother is far more likely to result than that of the child.

CARE should be exercised in making use of hydracetin in psoriasis. The application of a 20 per cent. ointment in lanoline proved effectual, but grave toxic symptoms ensued, consisting of exhaustion, weakness of the limbs, and a sense of impending illness, with mahogany-colored urine.

KILMER recommends that ointments should be made by dissolving the drug in oleite, to the amount of 25 to 33⅓ per cent. of the excipient, and then adding the fatty base. The oleite ointments are more absorbable than ordinary ointments. Oleite is chemically the sulpho-ricin-oleate of soda.

—*Amer. Druggist.*

KOCHER has advanced the study of goitre by showing that districts or families affected by it make use of water rich in organic material. Even in goitrous districts families who have a special supply of pure water are free from goitre. Tovel found very few microörganisms in the water which is used in districts free from goitre.—*Lancet.*

HEIDENHAIN states that the recurrence of mammary cancer is due to the presence of microscopic portions on the surface of the pectoralis major. The lymphatics in the retro-mammary fat are cancerous in two-thirds of the cases. If the tumor be closely connected with the muscle, the latter should be extirpated entirely; in other cases the superficial layer should be removed.—*Lancet.*

INCOMPATIBILITY OF ANTIPYRIN WITH CHLORAL HYDRATE.—M. Blainville, a druggist of Paris, having occasion to mix four grammes of antipyrin and five grammes of chloral hydrate in fifteen grammes of water, noticed that the liquid became milky in appearance; then became clear and deposited an oily liquid. Filtered, this liquid possesses neither the taste of antipyrine nor chloral; the odor resembles somewhat coriander seed. —*La France Médicale.*

INFLUENCE OF ALIMENTATION ON THE COMPOSITION OF MILK IN WOMEN.—Dr. St. Sycz. Zaleski (Dorpat) presents the following conclusions:

1. A milk too rich in fatty matters may exercise a deleterious influence on the health of the child.

2. An alimentation abundant and rich in albumen augments greatly the quantity of fatty matter contained in the milk; it diminishes the quantity of lactose, and has but little influence on the other elements.

3. A suitable diet will permit to a certain extent the obtaining of a necessary lacteal composition for each child in each particular case.

4. Alimentation exercises, therefore, a marked influence on the composition of the lacteal secretion, in man as well as in animals.

5. The fatty matters in milk are probably produced directly or indirectly from the albuminoid substances introduced by alimentation.—*La France Médicale.*

PRECAUTIONS AGAINST TUBERCULOSIS.—At the Congress for the Study of Tuberculosis, held in Paris last year, a commission was appointed to report a series of simple and practical rules for prophylaxis. The commission consisted of MM. Chauveau (President), Bartel, Cornil, Grancher, Landonzy, Lannelongue, Legroux, Leblanc, Nocard, Rossignol, Verneuil, Petit, and Villemin, who presented the report. This had been reviewed, and its conclusions approved by MM. Bouchard, Brouardel, Potain, and Proust. It will thus be seen that the instructions come with the sanction of the highest authority in France. The following abstract gives the essential points contained in the report, presented to the Academy of Medicine, on July 30:

Adverting to the fact that more than one-fourth of the deaths in Paris were due to tubercular disease, not pulmonary affections alone, tuberculosis was pronounced a parasitic malady, virulent, contagious, transmissible; caused by Koch's bacillus, which enters the body by the digestive canal with the food, by the respiratory tract with the inspired air, by the skin and mucosa through various solutions of continuity. Certain maladies and constitutional states predispose the individual to tuberculosis.

The parasite is to be found in the milk, the muscles and the blood of animals which serve as food for man. The use of meat, raw or slightly cooked, and blood, which can contain the living germ of tuberculosis, should be prohibited as food. Milk should only be used after being boiled. The tuberculous mother should not nurse her child, which should be brought up by a healthy wet nurse in the country. If milk be used as the infant's food, that of the ass or the goat is to be preferred.

A rigorous inspection of animals slaughtered for food should be enforced. The only absolutely certain means of avoiding the danger of meat from tuberculous animals, is to submit it to such thorough cooking as will affect the interior of the piece as well as the surface. Furthermore, the tubercle germ can be transmitted from a tuberculous person to a healthy one, by the sputa, pus, dried mucus, and all objects charged with tuberculous dust. In order to guard against this, it was adjudged necessary to know that the sputa of phthisical persons being the most potent agent in transmitting the disease, it is a public danger to eject them upon the ground, carpet, hangings, curtains, napkins, handkerchiefs, cloths and coverlets. The use of spittoons should be strictly enjoined. These should always be emptied into the fire and cleaned by boiling water. They should be never emptied upon dunghills, in gardens, where they could infect fowls, or in latrines.

Never sleep in the bed of a consumptive; frequent his room as little as possible, and especially, never allow young children to sleep there.

Banish from the homes of all consumptives, all persons who are predisposed to this disease.

Never use objects which may have been contaminated by tubercle, until they have been disinfected, by baking, under pressure, boiling, sulphur fumigation, or by the use of lime. Chambers occupied by consumptives should be furnished and draped in

such a manner that disinfection can be readily and thoroughly performed, after the departure of the patient. It would be better to have these rooms devoid of carpets, curtains and hangings; they should be whitewashed and the floor covered with linoleum.[1]

In discussing this report, M. Dujardin Beaumetz adverted to the importance of prophylaxis, in view of the successive disappointments which had ensued upon the use of medications directed against tuberculosis. He thought that the disease prevailed in the country as extensively as in the city; the statistics being better kept in the latter, and many cases coming into the city hospitals which arose in the country. A country residence once infected was more dangerous than one in the city, where people changed their homes more often and disinfection was more common. He thought the report put in the same category conditions of contagion the most hypothetical and those which were more certain and well known. For instance, the transmission of the tuberculosis by the food, he believed to be quite exceptional. Milk was rarely contaminated by tubercle bacilli because this necessitated the presence of tubercle of the mammary gland.

In M. Alexandre's report to the Council of Hygiene of the Seine, it was stated that during 1888 scarcely a dozen cows were found to be consumptive; and none of these had tubercular mammitis. This danger he consequently believed to be illusory, though, as milk could be easily boiled, without detriment, he did not object to it.

But in denouncing raw or slightly cooked meat, he thought the commission went too far. This would deprive cookery of its most attractive forms, and the physician of his best means of treating disease. Though the report spoke only of tubercular meats, yet in France the inspection was only thorough in the larger cities. The transmission of tubercle from meats to man had not yet been demonstrated; while experiments, even under the most favorable conditions, gave contradictory results. Out of Nocard's intraperitoneal injections in twenty-one series of guinea-pigs, with the fluids from the flesh of as many tuberculous cows, only once did he obtain a positive result.

But the gastric juice was a most active destroyer of the tubercle bacilli.

The danger from food could not be put in the same plane as that from sputa. He approved entirely of the prevention by the government of the sale of tuberculous meat.

M. Germain Sée discussed the report at length, presenting the following conclusions:

1. He rejected the idea of contagion, because it implied atmospheric contagion, and caused mental trouble.

2. He objected to the enumeration of bronchitic predisposition, and to the effeminate education of the hereditarily tuberculous, as a double heresy.

3. He would never consent to the suppression of roast meats and the substitution of meats boiled "*a outrance.*"

4. He accepted the moist sputa, because this was one of the elements of propriety which the physician should enforce as well as the surgeon.

5. He adopted the boiled milk, without enthusiasm.

6. The remainder of the report was unimportant; even as to the white-washing and the use of linoleum.

His summary was: Our first duty was to keep quiet concerning contagion; the next, to observe rigorously the rules for experimental propriety in the sick-room, and the laws of a physiological cuisine for the public.

M. Lancereaux believed that hygienic measures would cause tuberculosis to disappear as well as paludism or typhoid fever. He assented to most of the report; but warned against the application to man of conclusions drawn from experiments on animals, which differed in their susceptibility to the disease, Those who cared for consumptives, nurses, etc., did not suffer from it with unusual frequency, and if inoculation were so easy as certain experiments would seem to indicate, he ought not to be then in the tribune, as he had been many times inoculated. Other elements besides the use of milk contributed to swell the list of infant deaths from tuberculosis; such as their lodgings, bad food, and residence in "crèches" etc. Transmission from man to man took place under specially favoring conditions; heredity, denutrition, alcoholism especially.

His views are thus summarized in the *Revue de Thérapeutique:*

Tuberculosis was a malady of great frequency; especially in great centers of population; consequently it was necessary that the public should know the means of avoiding this contagion.

Two etiological factors presided at the genesis of tuberculosis: the predisposition of the organism and the penetration into this organ of a special parasitic agent.

Predisposition, which depended on multiple causes, proceeded especially from alcoholic excess and breathing too concentrated air.

The sputa were a frequent source of contagion, especially when dried. The same was true of the milk of an animal whose udder was affected and, in some cases, of the flesh of tuberculous animals. He believed that in all these cases it was necessary to take precautions, which, however, ought to give place to the following considerations: Seek by all possible means to prevent and repress alcoholic excess. Let the law insure to the workman in his shop and the pupil in his school, etc., the cubic air-space necessary for the needs of health.

M. Villemin made a reply to the principal arguments which had been brought against the conclusion of his committee, but evidently was not disposed to insist upon their full acceptance. The question was not pushed to a vote in the Academy; as it was decided to relegate the matter for further consideration to a new committee, composed of the principal partisans of the report under discussion, and of those who had opposed it. The committee appointed consisted of MM. Villemin, Verneuil, Cornil, Dujardin-Beaumetz and Germain Sée.

The report of this committee will be awaited impatiently.

[1] Annales d'Orthopedie, 15 aout, 1889.

THE ANTITHERMIC ANALGESICS. — Dujardin-Beaumetz reported to the Congress of Therapeutics upon the chemical constitution of these bodies, the relations between their chemical and physiological functions, their general and special physiological action, their functional classification, and their clinical applications, and wished to direct attention to the following points:

It is for the therapeutic clinic to decide upon the indication for each of the antithermics; for experimental physiology to examine the intimate action of each of them, and for the general therapeutist to study the atomic grouping, which causes in the aromatic series the conditions of an analgesic.

Since chemistry has constituted by synthesis a series of bodies, all belonging to the aromatic series, which furnished at first some powerful antiseptics, then some very active antithermics, then some analgesics, the number of these bodies seems to augment every day, and one discovery succeeds another with great rapidity. Some have even demurred at these discoveries, which make one analgesic scarcely known before another is substituted for it. This is unjust, and the number of drugs which may relieve pain, and so accomplish the words of Hippocrates, "To relieve suffering is a divine work," can never be too numerous.

What is important to do is to study the precise therapeutic indication for each of these substances, and the elective action of each. The phenomenon of pain is a complex syndrome, and when one comprehends that the analgesic which calms migraine is powerless against the pain produced by lesions of the nervous system, or that the analgesic useful to soothe the erratic nervousness is useless in the pain of rheumatism, there is then a new interest not to lessen the precious acquisitions made each day by the chemist, but to utilize them better.

The physiological problem is still more complex and more difficult, and covers questions of high importance. And first is that of heat-generation. Most of these analgesics are antithermics, and this new class of antithermic medicines has shown by their physiological effects how just was the thought of those who claimed that animal heat resulted from multiple acts, since we see these antithermics group themselves into three classes, according to the preponderance of their physiological effects. Some are antiferments, and combat hyperthermia as a process of fermentation. Others act directly upon the blood corpuscle and lower temperature by diminishing the respiratory power of the blood. The third will reduce hyperthermia by acting directly upon the cerebro-spinal centers and modifying the caloric centers of the cord. It is almost exclusively these last antithermics which possess analgesic properties.

But when one enters into the more minute study of their physiological and toxic action, one sees that certain of them act only upon the cord, others more particularly upon the medulla, and the others upon the cerebrum itself. It would be very important to fix precisely this elective action of the different antithermics upon the diverse sections of the cerebro-spinal axis. There would result some important consequences, from the point of view of the therapeutic application of these remedies, especially upon that which concerned certain convulsive neuroses.

If the discovery of the bromides has rendered some incontestable service in the cure of convulsive neuroses, it would be useful to find some remedies which could be substituted for this medication, and it is likely that in this particular group such substitute may be found.

The last point to be considered is more complex, and constitutes the most delicate subject of modern therapeutics. To find in the atomic formula of these bodies the relation which exists between this formula and the therapeutic effect of the substance is a point which should engage the attention of every therapeutist.

He can to-day, thanks to the progress of chemistry, modify readily the atomic group of a large number of these bodies, taken from the aromatic series. Already, for certain of them, the study has been made. I recall some of the changes in caffeine. One can, by introducing in the formula of caffeine either the atomic group ethoxyl, or even the methoxyl or the hydroxyl, modify the properties of this body, and transform the tetanus remedy into a convulsive remedy, and perhaps into an analgesant.

It would be important to study this same atomic group in the numerous bodies which constitute the class of antithermic analgesics, and to see if we cannot establish some general laws which will enable us, knowing once the constitution and the atomic group of known bodies, to know *a priori* their therapeutic properties.

From all the studies we have made upon the subject with Dr. Bardet, it seems to us that we can establish provisionally the following law, which permits us to appreciate the antiseptic, antithermic, and analgesic effects of the new remedies taken from the aromatic series:

The antiseptic effects belong to the hydrate derivatives (phenols, naphthols, etc.). The antithermic properties are dominant in the amidogene derivatives (acetanilide, kairine, thalline). Then the analgesics are found principally in those last amidogene bodies, where one can substitute for an atom of hydrogen an atom of a fat radical (dimethyloxyquinizine, acétphénétidine, methylacétanilide). —*Revue de Ther.*

DIMINUTION OF UREA IN CANCER.—Ranzier, in an inaugural thesis, takes up the question of hypoazoturia in cancer, an observation of Rommelaere. Malignant tumors, located anywhere, in time impair the nutrition; the result being a diminution of the excretion of urea, following the secondary infection of the economy. The more rapid is the recoil upon the nutrition, the more precocious is the hypoazoturia. Cancer, then, only becomes the cause of the latter after it has vitiated nutrition. Hence, in external cancers, this symptom is of little value, as the diagnosis is readily made long before the urea is lessened.

In cancer of the stomach, if for any reason the diagnosis remains unsettled, even at a late stage, the

sign is of real value; as the normal excretion of urea is, in effect, incompatible with the presence of a cancer in an advanced stage of development.

In malignant abdominal tumors, the sign is of less value, because tuberculosis or renal disease may also cause it. But the diminution of urea has always a disastrous prognostic significance when we come to consider the question of operative interference in abdominal cases.

In some cases fatal anæmic accidents have ensued, when there was no other reason to suspect latent renal disease than the small urea excretion. That this symptom constitutes a formal contraindication against surgical interference in abdominal cases, is the important conclusion of this valuable thesis.

—*La France Médicale.*

Preventive Treatment of Erysipelas.—M. Marc Sée read a paper before the Academy of Medicine, in which he stated that in 1885 he had obtained some excellent results from a permanent antiseptic dressing in which subnitrate of bismuth was the essential element, and which he had then used for six months. Since then he had continued to employ that form of dressing and had not observed a single case of erysipelas, although many patients under his care were under circumstances particularly favorable to the development of this complication.

As a result he expresses such confidence in the efficacy of subnitrate of bismuth, even after operations in which the wounds were certainly non-aseptic, that he was satisfied not to use the careful irrigation usually followed, but after removing blood clots simply filled the wounds with bismuth or covered with absorbent cotten.

Not only will bismuth prevent erysipelas, but it is also an excellent method of treatment for erysipelas, when developed. In this case it is sufficient to cover the affected part with a thick coating of bismuth.

—*La France Médicale.*

The Contagion of Syphilis during the Tertiary Period.—At the Congrès de Dermatologie et de Syphilographie, M. Landouzy reported the two following cases: in the first, a male syphilitic, married three years after the appearance of the last specific symptom, and communicated a vaginal chancre to his wife. The second case was a man who had been treated twenty years previously by Ricord; had just been married; when, after a few months, he presented a lesion on the penis, which M. Fournier diagnosed as a gumma; this patient communicated syphilis to his wife. M. Hardy made mention of two similar cases.

M. Fournier relates the case of a man, who, having had syphilis fifteen years previously, marries while at the time suffering from an ulceration of the tongue which has proved obstinate to all treatment. As this patient indulged in smoking to a great extent, notwithstanding the advice of M. Fournier, he, in two years' time, communicated the disease to his wife, who presented a chancre of the inferior lip—*La France Médicale.*

Disinfection of Localities by Sulphurous Acid Gas.—M. H. Dubief, chief of the bacteriological laboratory, M. I. Brusl, and M. Gaillard, after a most extended series of experiments, arrive at the following conclusions:

1. Sulphurous acid gas has a most decided microbic action upon the germs in the atmosphere.

2. This action is most actively exercised in the presence of moisture.

3. The action of sulphurous gas is very manifest upon germs perfectly dried.

4. The action of sulphurous gas in the air makes itself felt upon the germs of bacteria. It seems to respect in a certain measure the cryptogamous spores which are less susceptible to dilute acids.—*Bul. Général de Ther.*, Aug. 30.

Syphilitic Alopecia.—M. Besnier, at the Hospital St. Louis, advises the following treatment:

The hair is to be worn short, a condition necessary for success. For this reason the treatment is more prolonged in women, who will not submit to the above. In the morning, after washing with soap and warm water, the following pomade may be applied:

℞.—Salicylic acid . . . . . 2 grammes.
Precipitated sulphur . . . . 12 grammes.
Lanoline,
Vaseline . . . . . aa 50 grammes,

At night, friction with the following liniment should be made with a soft brush:

℞.—Alcohol of rosemary . . . 100 grammes.
Tinct. of cantharides . . . 10 grammes.

If the hair is naturally greasy, we may use the following powder to dry it:

℞.—Acid salicylic . . . . . 1 gramme.
Starch . . . . . 100 grammes.

—*Journal de Médicine et de Chirurgie Pratiques.*

Vaccinal Syphilis.—M. Herrieux presents five cases of syphilis following vaccination, which occurred in his practice. The most searching inquiry showed the subjects to have been perfectly healthy; nor can the fault be laid to the instruments used, for all precautions were taken. M. Herrieux claims that Jennerian vaccine should not be given up on this account, as accidents such as septicæmia sometimes follow the use of animal vaccine when not fresh. This does not take place with human vaccine, as it will preserve for a long time without alteration.—*Bulletin de l'Académie de Médicine.*

Richardson says that vaseline with morphine added forms one of the most soothing applications for cutaneous affections with painful ulceration. He recommends the following formula:

Pure vaseline . . . . . 30 gram.
Chloroform . . . . . 8 "
Morphine . . . . . 0.20 "

The chloroform allows a large quantity of morphine to be incorporated and assures its division in the mass. It is applied upon soft linen and renewed every twelve hours.—*Gazette de Gyn.*

Medical News and Miscellany.

LAST year 1356 persons died of delirium tremens in England.

IN nineteen towns of Connecticut not a single death occurred last week.

ENTERIC FEVER is said to be epidemic at Cairo among the soldiers in garrison.

SEVERE illness and one death was caused at Susquehanna by the eating of wild parsnips.

THE freshest ailment is an affection of the fingers due to constantly thumping a type-writer.

THE Polyclinic has awarded the contract for the erection of their new college, hospital and dispensary building on Lombard Street.

EX-SURGEON GENERAL JOSEPH BEALE, of the United States Navy, died at his late residence, 2029 Arch Street, aged seventy-five years.

DR. HUIDEKOPER, a leading authority in veterinary medicine, says that half the consumption in the country is due to tuberculous cattle.

DR. R. S. HUIDEKOPER, of this city, presided at the annual meeting of the United States Veterinary Medical Association, held in Brooklyn.

CALEB B. TOZIER, whose life, with a fracture of the cervical vertebra, was so remarkably prolonged, died of exhaustion in the Cooper Hospital, Camden.

THE Boston *Courier* says that the remarkably high death-rate in that city this summer is mainly due to the impure water which the citizens are compelled to drink.

ENGLISH medical experts are now making strong arguments in favor of the corset. Thus, little by little evidence accumulates to show that the corset has come to stay.

THE Sultan has summoned Dr. Schwenninger to Constantinople, and built a palace for him so that he may stay for a week and apply his treatment in reducing the Sultan's obesity.

A SWINDLER has been going from one drug-store to another in the city, ordering the most expensive medicines and then charging the account to some physician in the neighborhood.

AT the last meeting of the Philadelphia County Medical Society Rev. Dr. H. L. Wayland delivered, by invitation of the directors, a lecture on "Some of the Liabilities of the Medical Profession."

DR. AUGUSTUS WALLER has recently made a number of experiments, showing that it is possible to detect, by existing electrical instruments, the electric currents generated at each beat of the heart.

THE Jefferson Medical College and Hospital will soon add a third building to the two already owned by it, and this structure will be erected on Walnut Street, between Tenth and Eleventh, on the north side.

AT the meeting of the Executive Committee of the Congress of American Physicians, held at the College of Physicians, Dr. S. Weir Mitchell was elected President of the Congress which is to convene in 1892.

A RECENT writer, M. Ungerer, expresses his belief that the perfume of flowers, and their essences, have a healthy effect on the constitution, and that residence in a perfumed atmosphere tends to prevent pulmonary affections.

THE Civil Service Examining Board will meet at their rooms in the new City Hall upon Wednesday, October 9, at 11 A.M., for the purpose of holding a competitive examination of candidates for the position of Resident Physician, Insane Department, Philadelphia Hospital.

To Contributors and Correspondents.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, United States Army, from September 24, 1889, to September 30, 1889.

POPE, BENJAMIN F., Major and Surgeon. The leave of absence granted, by direction of the Secretary of War, in S. O. No. 54, August 17, 1889, Department Texas, is extended one month. Par. 6, S. O. 224, A. G. O., September 26, 1889.

LORING, LEONARD Y., Major and Surgeon. By direction of the Secretary of War, the station is changed from Fort Mojave, Arizona Territory, to Fort Wingate, New Mexico, and he will report for duty at the latter accordingly. Par. 7, S. O. 219, A. G. O., September 20, 1889.

ADAIR, GEORGE W., Captain and Assistant-Surgeon. Is granted leave of absence for one month. S. O. 90, Headquarters Department of the Platte, September 25, 1889.

BURTON, HENRY G, Captain and Assistant-Surgeon. Will report in person, by direction of the Secretary of War, on the expiration of his present sick leave of absence, to the commanding officer, David's Island, N. Y., for temporary duty at that station, and by letter to the Superintendent of Recruiting Service. Par. 3, S. O. 223, A. G. O, Washington, September 25, 1889.

CHAPIN, ALONZO R., Captain and Assistant-Surgeon. Leave of absence for fourteen days is granted, with the approval of the Secretary of War. Par. 10, S. O. 223, A. G. O., September 25, 1889.

Changes in the Medical Corps of the United States Navy for the week ending September 28, 1889.

GORGAS, A. C., Medical Director. Detached from Examining Board and ordered to Hospital, Philadelphia, Pa.

HORD, W. T., Medical Director. Detached from Hospital, Philadelphia, Pa., and wait orders.

BOGERT, E. S., Medical Inspector. Detached from New York Navy Yard and ordered to Examining Board.

MCMURTRIE, D., Surgeon. Detached from U. S. S. "Vermont" and ordered to Navy Yard, New York.

BABIN, H. J., Surgeon. Ordered to the Receiving-ship "Vermont."

HALL, C. H. H., Passed Assistant-Surgeon. Resigned from the Naval service, to take effect November 1, 1890, and resignation so accepted.

Clinical Lecture.

AMPUTATION OF THIGH FOR ELEPHANTIASIS ARABUM.

BY JOHN W. CROSKEY, M.D.,
Chief of Clinic, Medico-Chirurgical Hospital.

(Reported by GRIFFITH J. THOMAS.)

GENTLEMEN: In the absence of the surgeon of this clinic, Prof. Goodman, I have the honor of appearing before you to-day with a case no less interesting than it is rare in this country and latitude. The patient came under my observation about one month ago. The leg presented the enormous size that you now witness, and bears, as you see, a marked resemblance to the leg of an elephant. It measures seventeen inches around the calf. The integument is white and lustrous, and upon closer inspection the epidermis is seen to be desquamating, a condition produced by lack of nutrition, consequent to the hypertrophy of the skin and subcutaneous tissue—the structures pathologically involved in this affection in connection with the lymphatics. To affections of this kind the name elephantiasis is given, a name significant of the enormous hypertrophy of the affected part. To designate the different varieties of the disease, epithets are used which are chiefly the names of the different countries in which the disease occurs in its various forms. Thus, the case before us corresponds more closely with the kind known as elephantiasis arabum, which prevails chiefly among the Arabians, and in whose country it is believed to be hereditary and contagious. It is, as I have already remarked, a chronic hypertrophy of the skin and subcutaneous tissue, occasioning enormous enlargement and deformity. It is supposed to be the result of repeated attacks of inflammation of the lymphatics and skin. The term elephantiasis is applicable to any enormous hypertrophy of the skin from whatever cause it may arise. It is not common in this country, but is endemic in tropical countries. It occurs more frequently in males than in females, and affects those who are poor and ill fed rather than those who are well fed and obey the laws of hygiene.

When the disease first appears there are severe constitutional symptoms, resembling those of intermittent fever. Inflammation of the part usually follows the fever, and the skin becomes red, tense, tender, attended by an intense burning sensation and discharge of a serous or chyle-like fluid, and, on the whole, presenting all the characteristics of an attack of erysipelas. These symptoms subside, but the part remains swollen and distorted, although free from pain and heat. The condition of the limb after the first few attacks, is apparently œdematous, pitting upon pressure, but after several attacks the part becomes hard and dense, with an anæsthesia of the skin. In the case before us the inflammatory condition still exists, and that stage has not yet been reached when heat and pain are absent, since the patient cannot endure the pressure of his clothes upon the limb, all that he can bear upon it being a

piece of mosquito bar. The disease is rapidly extending up the limb, and to stay its progress is the object of the operation to be performed before you to-day.

To the naked eye a section through a limb affected with elephantiasis arabum presents an appearance of layers, enormously thickened, of the corium, subcutaneous tissue, fasciæ and periosteum. The muscles, however, become atrophied from long continued pressure and want of use. As to the treatment of this disease, it can be said that medicines have little or no effect upon it. Martin's elastic bandage has been used successfully in the prevention of the hypertrophy. Electricity has also been tried with some success. Compression of the main artery by digital pressure, ligation of the main artery, and section of the nerve, are other methods that have been tried. The latter was done in the case of a negro, aged fifty, at the Pennsylvania Hospital, in this city. He had elephantiasis of the right leg. Dr. Morton excised a portion of the right sciatic nerve. The operation was followed by a rapid diminution in the size of the leg, the calf being reduced from twenty-three inches to seven inches in seven weeks. This patient, some time after the operation, was attacked by pleuropneumonia, and later by a deep-seated suppuration in the opposite limb. The pulmonary trouble developed into a catarrhal phthisis, from which he died five months after the section of the nerve. Amputation is another mode of treatment by operative means, and such an eminent authority as Agnew tells us that only excision and amputation appear entitled to confidence.

Our patient presents a very interesting history, which I will read: Capt. Chas. D. Foy, born at Downingtown, Pa., aged sixty-three years. Served in the Mexican war, during which he was wounded in the knee. Later, served in the war of the Rebellion. While quartermaster at Falmouth, Va., was accidentally thrown from a train, sustaining a fracture of the os calcis of the left foot, on account of which he was laid up in a hospital for three months. Upon being discharged from the hospital he returned to the front, but was unable to endure long marches, as his foot thereby became weak and painful. Upon expiration of the period of his enlistment he came to Philadelphia, and placed himself under the treatment of an electrician, who did him so much good that he returned to the front once more. He was not actively engaged, however, during his second enlistment, but his foot began to grow worse, giving him much pain. Returning to the city in 1865, he again tried electrical treatment, but experienced no relief. About a year later his ankle began to swell, attended with an increase of pain. He was engaged for many years as a railroad conductor, but was obliged to give it up on account of his leg, which continued to enlarge from the time the swelling first began in the ankle. As the leg grew in size, it also grew more painful. In 1885 the leg began to grow more rapidly. It soon became so cumbersome that patient was unable to go around. The pain also became so intense that the pressure of clothes upon limb could not be endured. In 1886, suppuration set in, and pus was freely discharged from two openings beneath the internal malleolus. These running sores continued for six weeks, when they dried up. In 1887, upon recommendation of the Surgeon-General, he consulted Prof. Goodman, who advised him to have the limb amputated, when it could have been saved about six inches below the knee. Vainly hoping for relief, he deferred having it done. But within the last two years the limb continued to grow worse, increasing in size, the swelling gradually ascending. It would frequently break down into suppurating sores, which would discharge a while and then dry up. The skin became very much thickened, and covered with small vesicles containing a serous fluid. He has been unable to go about the house, being obliged to sit in the one place continuously. In this condition I found him, and at his request he was brought to this Hospital to have done that which it would have been wise to do two years ago. He has been in the Hospital about a week, during which time especial attention has been paid to getting him in that constitutional condition best calculated to endure to-day's ordeal.

The patient being now well under the influence of ether, the leg is held up to allow it to be drained of its blood, as the patient needs all the blood we can possibly preserve him. Ordinarily, we would apply a Martin's bandage to the whole limb to a point a little above the line of amputation, but owing to the condition of the limb, the bandage is applied just from the knee up. The Martin's bandage drains the blood more thoroughly from the part to be removed than it can possibly be done by manual pressure. To control the hemorrhage incident to the operation, we apply a tourniquet, with the pad pressing upon the femoral artery. We will make antero-posterior flaps of the integument and fasciæ, and circular of the muscle, in the lower third of the thigh. In this wise we secure two things that are desirable, viz.: cicatrix, or line of union, behind the bone, and the section of nerves and vessels at right angles to their main axis. We will ligate with chromatized catgut, the vessels which we find are difficult to ligate in this case, being in an atheromatous condition. The hemorrhage being stopped, we apply, before closing the wound, boroglyceride to the raw surfaces to secure asepsis. The flaps are sutured together with softer catgut, which we will also use for drainage. The wound will now be dressed antiseptically with iodoform and bichloride gauze. The dressing is not to be removed until complete union has taken place, unless suppuration sets in, which, should it occur, will be indicated by a decided and continued elevation of temperature.

The following is the daily record of the case after the operation, from which it will be seen that the dressing was retained twelve days before being removed:

August 29.—Evening temperature, 99° F.

August 30.—Morning temperature, 98.8° F.; evening temperature, 99.4° F.; one movement of bowels by injection. Was given the following: Hydrarg. chlor. mitis, gr. j; sodii bicarbonatis, grs. xi; sacchari albi, q. s. m. ft., chart No. VI. One every hour.

August 31.—Morning temperature, 99° F.; evening temperature, 102.4° F. Continued at this point for

about an hour, then fell to 100.6° F. One movement of bowels by injection.

September 1.—Morning temperature, normal; evening temperature, 99.4° F.

September 2.—Morning temperature, normal; evening temperature, 99.8° F. Was given elix. quininæ, ferri et strychninæ, teaspoonful thrice daily.

September 3.—Morning temperature, normal; evening temperature, 99° F. One movement of bowels.

September 4.—Morning temperature, normal; evening temperature, 99.2° F.

September 5.—Morning temperature, normal; evening temperature, normal. Two movements of bowels.

September 6.—Morning temperature, normal; evening temperature, normal.

September 7.—Morning temperature, normal; evening temperature, 99° F. One movement of bowels.

September 8.—Morning temperature, normal; evening temperature, 99° F.

September 9.—Morning temperature, normal; evening temperature, 99° F. One movement of bowels; some little discharge from dressing; removed; perfect union; no suppurating points; catgut drainage entirely absorbed. Redressed.

September 10.—Morning temperature, normal; evening temperature, 99° F. Two movements of bowels, morning and night; patient sitting up.

September 11.—Morning temperature, normal; evening temperature, 99.4° F. One movement of bowels.

September 12.—Morning temperature, normal; evening temperature, 99.4° F. One movement of bowels.

September 13.—Morning temperature, normal; evening temperature, 99.8 F.

September 14.—Morning temperature, normal. Two movements of bowels. Patient looks and feels well, and is rapidly going on to recovery.

RHEUMATIC PERICARDITIS.

(Read before the Chicago Pathological Society, September 9, 1889.)

By JOSEPH M. PATTON, M.D.,
CHICAGO, ILL.

In considering the subject of rheumatic pericarditis, I have endeavored to confine myself as closely as possible to pericardial inflammation of rheumatic origin; but as the distinction is chiefly an etiological one, the symptoms and course being much the same as in pericarditis arising from other causes, you will pardon such general observations as are necessary in the elucidation of the subject.

Etiologically, inflammation of the pericardium stands in much the same position as it did ten years since, the pericardium having generally escaped investigation in the hunt after microbes. Recently this subject has been investigated in a few instances; one observer has succeeded in inducing pericarditis through culture from an inflamed pericardial surface, in a pericardium previously irritated by turpentine; the relation between cause and effect, in this instance, is rather characteristic of some of the theories given in regard to the etiological relations of micro-organisms and disease. Bacteria have been found in the products of pericardial inflammation when they were not present in the blood. The most we are warranted in assuming at present, is that microbes in the system may produce some poisonous substance or alteration in the tissues or the blood, so as to result in inflammation of that point in the physical economy, which, for the time, is below the power of successful resistance. The artificial production of such a point previous to the introduction of a microbe simply proves that they will attack such a point, and not that they will actually produce it. The doctrine of *phagocytes* is a tempting one in this connection—that to a destruction of phagocytic cellular action is due the production of a point of deficient resistance. At all events, the necessity for a specific bacillus for the production of pericarditis is not recognized as yet.

In regard to rheumatic pericarditis, we know as much as we do about rheumatism. According to Bamberger, about 30 per cent. of the cases of pericarditis occur in connection with acute articular rheumatism. Clinically, we are not able to tell which cases are liable to this complication, further than that it more often occurs in those where several joints have been successively attacked, and the rheumatic manifestations shifting in character. Da Costa states that endo- and pericarditis generally attend each other, and that pericarditis without endocarditis is more frequently met with than the contrary condition. This statement is misleading; proportionately, it may be true, but actually endocarditis, uncomplicated by any other cardiac lesion, is much more frequently obtained in rheumatism than is a similar condition of the pericardium. Debilitated persons are more likely to have pericarditis complicating rheumatism than robust persons; in the latter the cardiac trouble is generally endocarditis.

Pathologically, the cause rests in an inflammatory nutritive derangement, resulting in proliferation of the pericardium, interstitial exudation, or free exudation, plastic, or serous, depending upon the condition and extent of the inflammatory process. The anatomical changes wrought in the pericardium are important, and have much to do with our prognosis. The small hypertrophies of the connective tissue—subepithelial, as well as the whitish tendinous spots called by Sehnenflecke *maculæ albidæ lactæ*, are of no clinical interest. The vascular injection of the tissue, loss of epithelium and of luster, the villous appearance due to proliferation of young connective-tissue cells, the exudation of serum, clear or flaky, or heavily charged with fibrin, which may become fibrillated on the walls of the pericardium—cor villosum or cor hirsutum, the latter being the condition most frequent in acute articular rheumatism; these appearances are all familiar and need not be dwelt upon. When the plastic exudation has been considerable, thickening of the pericardium may result from connective-tissue organization, incomplete absorption of the inflammatory products; there may be masses of cheesy material covering the thickened fibrous pericardium. This condition will be further considered hereafter. Small amounts of effusion are said to accumulate around the base of the heart, but unless there

should be adhesions limiting the pericardial space, I do not see why this should be. Large amounts of effusion may distend the sac, interfering greatly with cardiac motion, besides softening the cardiac tissue. Myocarditis frequently results from inflammatory extension; ventricular dilatation may result from weakening of muscular tissue.

The subjective symptoms occurring in the course of acute articular rheumatism are not at all characteristic. There is nothing to particularly emphasize the onset. As a rule, there will be no rigor, little or no additional rise in temperature; the pulse may be accelerated or retarded; pain to the left of the epigastrium, and over the cardiac region, palpitation and dyspnœa are the chief signs, yet they may be absent. Again, the symptoms may be marked, with a sense of impending danger. The pain is dull or lancinating in character, and when excessive is due to pleurisy. The palpitation varies in character. In the early stages there may be forcible, irregular, irritable heart's action, which is not due to loss of muscular integrity. This palpitation is at times pronounced, and while it may be a theoretical explanation only to ascribe the cause to irritation of the cardiac ganglia, it is still the most plausible one that can be advanced. The three largest of the minute ganglia, which are found on the nerves in the heart tissues, are the ganglion of Bidder, near the mitral valve; the ganglion of Ludwig, in the inter-articular septum; and the ganglion of Remak at the mouth of the vena cava. According to Kolliker, they are connected only with the sympathetic; according to Beale only with the fibers of the vagus. The afferent branches furnished by the vagus are cervical and thoracic. The first, second, and third cervical nerves anastomose with the carotid plexus of the sympathetic and inferior laryngeal; the thoracic branches with the cardiac filaments of recurrent and branches of great sympathetic. The middle cardiac nerves of Hirschfeld are an indirect communication by way of the recurrent, anastomosing with superior cardiac nerves of vagus and with the sympathetic. The superior, middle, and inferior cardiac nerves of the sympathetic from the superior, middle, and inferior ganglia and first thoracic ganglion anastomose with each other, with laryngeal plexus and the cardiac thoracic branches of vagus. Physiologists have described centripetal branches with the depressor nerve of Cyon, centrifugal branches with the accelerator nerve of Cyon, and accelerator branches from the spinal cord going to loop of Vieussens—a double branch connecting last cervical ganglion with the first thoracic ganglion—which, according to Bezald and Cyon, is the center of accelerator nerves. These various nerves, with their intricate series of plexuses and planes of communication, serve to make any direct theory, as to the exact route of a nervous influence, more or less problematical. It would seem, however, in view of the various symptomatic cardiac disturbances which arise in a reflex manner, as from the stomach, that the irregularity is one which involves the cardiac portions of the sympathetic; and if the cardiac ganglia belong to this system, and they probably do, then irritation of these ganglia may be the cause.

With much effusion the heart's action is wavy and indistinct, conveyed over a considerable area; with muscular degeneration and dilatation there is labored cardiac action, lifting a considerable portion of the cardiac area, with some epigastric motion, the whole being out of proportion to the vascular tension.

Dyspnœa may result from passive congestion of the lung, or from pressure or effusion, and from the latter cause may be very severe, when there is comparatively little disturbance of cardiac action. The patient assumes that position which allows of the freest action of the right lung.

Every case of acute rheumatism should be carefully and frequently examined for pericarditis, as it may come on so quietly as to allow of the accumulation of a large effusion before it is discovered.

Inspection will reveal the character of the cardiac action as given above, or there may be some bulging of the cardiac region with large effusion in young subjects; in older persons ossification of the cartilages may prevent this. Palpation reveals the above conditions, the apex may be in the proper position, or may be displaced, it may be forcibly, or almost imperceptibly, and somewhat lower down as the effusion distends the sac. Bending forward and allowing the heart to gravitate against the chest wall may increase the force of the impulse.

Percussion is negative unless there is effusion; if the effusion is small in quantity, there would be a line of dulness extending from the fourth rib to the apex, obliquely beneath the sternum, and would be very difficult of detection. Some writers claim that small effusions give dulness about the base of the heart, at or above the second rib. This view, I believe, is due to faulty appreciation of the anatomical conditions. In a number of autopsies which I have made, where there were several ounces of fluid in the pericardial space, I had not observed dulness over the base, and in most instances was not able to diagnose the presence of fluid *ante mortem*. Rotch gives dulness to right of sternum in fifth intercostal space as a valuable sign in small effusions; with a healthy heart this may be a useful sign, but with right ventricular hypertrophy it would probably be difficult to determine its value. Large effusions give pyramidal dulness, extending from the second to the sixth, and from the right of the sternum to the left of left mammary line. The dulness may change somewhat with changed position, the lung closing over the heart as it gravitates backward in the recumbent position, and lessening the area of dulness, or the compression of a large effusion may allow of no change; in this instance the heart may gravitate back within the sac, and by forcing the fluid forward distend the sac one-third larger than in the erect posture; extension of dulness to left of apex beat may give good evidence of effusion. Auscultation gives the most distinctive sign when it can be obtained, and it generally is present in rheumatic pericarditis. This is the friction sound. This sound is synchronous with the heart sounds, but is longer, and can be heard after their cessation; it is harsh, grating or creaking in character, and may at times be very difficult of detection. It is heard over the ster-

num from the second to the fourth rib, is increased by bending forward, and diminished in the recumbent position. It may be present during a portion, or the whole, of the disease; also when there is considerable fluid present, it is then heard about the base of the heart. Great distention of the sac by fluid may displace it entirely. The friction sound is to be distinguished from valvular murmurs, pleuritic frictions and cardio-respiratory murmurs. From valvular murmurs differentiation is easy; their character, direction of transmission, and other evidences of organic disease will prevent confusion. From pleuritic friction the cessation of sound with suspension of respiration affords a clear distinction. Here it must be borne in mind that pleuritic friction may be caused by cardiac action, and would then continue during suspension of the respiratory act. The so-called cardio-respiratory murmurs, inspiratory and expiratory, produced in the tongue of lung overlying the heart, and caused by the impulse given the air in the lung by the cardiac systole during expiration, cardio-expiratory, and by the suction action of the vacuum, caused by the systole during inspiration, cardio-inspiratory, can hardly be mistaken for pericardial friction by one accustomed to the sound; still as they occur at the same time they should be remembered. They, of course, cease during cessation of respiration.

The heart sounds may be exaggerated, or when there is much effusion, very distant and indistinct. This faintness of the heart sounds, entirely incompatible with the action of the heart and tension of the vessels, is one of the most characteristic signs of pericardial effusion. Intensification of the second sound over the aortic area is at times quite marked. If, during the course of acute articular rheumatism, the heart becomes irritable, with palpitation and precordial pain, it should be carefully and frequently examined. Your examinations may be negative, and then you will find a friction sound developing, or you may find suddenly all the evidences of extensive effusion, or the effusion may come on gradually, displacing the friction sound, or the friction may remain, the dulness gradually increasing.

There are other forms of pericardial inflammation which may be confounded with conditions not mentioned, but they do not properly come within the bounds of this paper. Chronic pericarditis with adhesion of pericardial surfaces may result from the acute form; this occurs where there is considerable plastic effusion. This may not disappear as rapidly as a sero-fibrinous or serous effusion; the young connective tissue organizes rapidly, until there may be a firm mass of fibrous tissue surrounding the heart. The parietal layer is usually more thickened than the visceral; the two may be bound together by bands of tissue, or they may be almost entirely agglutinated; the epicardium may be transformed into plates or masses of bony hardness. The possibility of this condition must be borne in mind in making a prognosis where recovery is slow, as the additional labor imposed on the heart under the circumstances may cause hypertrophy.

Various signs have been given as diagnostic of this condition, such as a lack of alteration in the area of percussion dulness in inspiration and expiration, sinking in of intercostal spaces, and end of sternum with systole of heart; but there are no characteristic signs of this condition.

The treatment is, to a large extent, symptomatic. In recent cases of rheumatic pericarditis, it is well to adopt an expectant line of treatment. If the onset is active with great pain, the local application of a dozen leeches will give great relief. Digitalis, when the heart's action is labored, is very useful; it should be given carefully, and if myocarditis be present, very sparingly or not at all, as it would be impossible to give enough to be of any use without danger of toxic results. Iron and a nutritive diet are necessary. Iodide of potassium, with the bicarbonate (when the more active rheumatic trouble has already been controlled), is very useful. Rest should be strictly enjoined until exercise can be taken without cardiac excitement. Paracentesis should be performed when pressure from the effusion causes great dyspnœa, or interferes greatly with the action of the heart. The operation may be performed with a trocar, by incising the skin in the fifth intercostal space about an inch from the left edge of the sternum, and passing in the trocar; the stylet should be sheathed as soon as the pericardium is reached; the trocar being passed obliquely, the canula can then be pushed further in, if necessary. The aspirator is the preferable instrument for this operation; a needle about one millimetre in diameter should be used; or if the diagnosis of the quantity and location of fluid is not clear, one-half as large as puncture of the heart would then probably cause no trouble. The reversible aspirator, with siphon attachment, is preferred by some, as the fluid may be flaky and obstruct the needle, in which instance the action may be reversed and the needle cleared without removal. The patient may be in the sitting or recumbent position. The precise spot for introduction of the needle varies according to the ideas of the operator. Some prefer the fifth interspace, an inch or inch and a half from left edge of sternum; others prefer the very apex of the space between the free end of the sternum and the cartilage of the ribs. This is a good point in proper cases, the diaphragm is attached just above this point, but the weight of a considerable effusion may push it down sufficiently to allow a needle inserted in the apex of this space to pass through its tendinous insertion into the pericardium. The space existing between the muscular slips, which attach the tendinous insertion of the diaphragm to the cartilages of the ribs on either side, and which is filled by areolar tissue, probably lessens the resistance at this point, and allows the pericardial sac to descend lower than it otherwise would; but with a small effusion it would probably be easier to obtain fluid in the fifth interspace. As soon as the point of the needle is well engaged in the tissues, the stop-cock should be opened, allowing the vacuum to extend to the needle point, as the first intimation of being into the sac may be the presence of fluid in the tube. As a rule, however, the sensation of non-resistance conveyed to the hand in pushing the needle, will tell plainly when the pericardial space is entered. Be-

tween sixteen and eighteen ounces of fluid have been removed at one aspiration. The instruments should be aseptic, and care should be taken that they be in good working order. This operation may be demanded simply as a palliative in cases where death must shortly ensue, and the relief obtained from it fully justifies the small risk which may attend it.

A CASE OF ENORMOUS FIBRO-CYSTIC TUMOR OF THE UTERUS.

LAPAROTOMY—RECOVERY.

By X. O. WERDER, M.D.,
PITTSBURGH, PA.

JUNE 14 last, I was consulted by Miss W. C., aged twenty-three, in regard to an abdominal tumor which had been growing for the last eight months. The abdomen was enlarged to the size of pregnancy at full term, and below the umbilicus were a number of striæ, such as you find at the end of gestation. The right side of the abdomen was more rounded than the left, the tumor apparently having developed from that side. Dulness extended from the pubes to the ensiform cartilage, and to both hypochondriac regions, leaving a tympanitic area in both flanks. The tumor was uniform, soft and elastic, and distinctly fluctuating. The largest circumference of the abdomen was between the umbilicus and pubis. Digital examination per vagina revealed a normal nulliparous cervix, high up in vagina; fundus uteri could not be felt; sound was not introduced. Vaginal examination very difficult and painful on account of a rather rigid hymen. Examination per rectum negative.

Miss C. first menstruated at thirteen years, always regular and painless, lasting five days. Has been more profuse since appearance of tumor than before. Had typhoid fever five years ago, then dyspepsia for a time after, but not since. Was confined to bed with rheumatism eight weeks; otherwise in good health. No sign of tumor until eight months ago, and then it was only noticeable about two weeks before each menstruation, when she felt bloated; this feeling always disappeared before the next menstrual period. She was not conscious of the tumor, however, until two or three months before the operation. The tumor never gave her any trouble except about two weeks after each menstruation, when it always became distinctly larger, making her quite uncomfortable. From this history, and from the fact of the rapid growth of the tumor, and its apparent development from the right side, I did not hesitate to pronounce it an ovarian cyst. Several physicians of ability, who had examined the case before I did, had already made the same diagnosis.

June 24, I opened her abdomen at Mercy Hospital. The tumor was covered by a fold of the peritoneum, traversed by a large number of bloodvessels, some of them of enormous size, and studded by numerous small cysts. It was at first rather difficult to determine whether this was the omentum adherent to the tumor, or some other structure, but on pushing my hands down between the tumor and the abdominal walls, I could feel it spread out on each side of the tumor like two wings. There was, therefore, no doubt that it was the broad ligament which was enveloping the lower portion of the tumor. This fact, in addition to the tumor—which though even now distinctly fluctuating, seemed to have a thick-set muscular wall, a fold of which, picked up between the thumb and finger, felt like the walls of an enlarged pregnant uterus—made it evident that the growth was something else than an ovarian cyst: that it was either a pregnant uterus or a soft tumor growing from the uterus. A hypodermic needle was passed into the tumor, but nothing but a few drops of serous fluid was withdrawn. Pregnancy was excluded on account of her regular menstruation, rigid hymen and virginal condition of vagina and cervix, appearance of her breasts, absence of fœtal sounds and ballottement, etc. Concluding that we had to deal with a myoma, we proceeded to deliver it. This, however, was a difficult task. The abdominal incision was enlarged above and below, some adhesions to bowels and abdominal parietes were tied off as they were encountered, but all attempts to deliver the tumor failed until the incision had been carried up to the ensiform cartilage. By all these manipulations a great deal of time had been consumed before the tumor had been rolled out of the abdominal cavity, and the hemorrhage was alarming because of the extremely vascular nature of the tumor. The patient had become very anæmic, and at times almost collapsed, requiring constant stimulation by hypodermic injections of whiskey, of which she received from thirty to forty during the operation. The broad ligaments, the right of which reached higher on the tumor than the left, and folds of peritoneum connecting the bladder and the tumor were now separated from the tumor as far as necessary to form a pedicle, and were secured by small forceps and an elastic ligature passed tightly around the tumor, just above the attachment to the fundus uteri, and the myoma cut off above the ligature. After trimming the pedicle, which was about the size of two fists, it was brought into the lower angle of the abdominal wound, and the parietal peritoneum stitched to it just below the elastic ligature, in order to shut it off from the peritoneal cavity. The broad ligaments and the peritoneal folds, secured by the artery clamps, were also brought out below the pedicle; the forceps, six in number, were not removed, but were wrapped in iodoform gauze. In the absence of proper instruments for extra-peritoneal treatment of the pedicle—I having been prepared for an ovariotomy only, and not for a myomectamy—I compressed the upper part of the pedicle by two large Spencer Wells' forceps, one on each side, covering their handles with iodoform gauze. They were made to take the place of the clamps ordinarily used in the treatment of the pedicle by the extra-peritoneal method. The abdominal wound was then closed by silk-worm gut sutures, deep and superficial, a glass drainage tube was inserted immediately above the pedicle, the wound was covered with iodoform, and an antiseptic dressing was applied. The pedicle was seared with the actual cautery and covered with iodoform.

The patient rallied well from the shock of the operation, On the first evening temperature was 102°, pulse 120; afterward the temperature never reached that point again, and became normal after the first week. The patient suffered very little pain, except from flatulency the first few days; the large Spencer Wells' forceps attached to the pedicle gave her most of her trouble, as they prevented her from turning on either side, keeping her constantly in the dorsal position. The drainage tube was removed about thirty hours after the operation. The small artery forceps attached to broad ligaments and peritoneal folds were removed on the seventh day; large Spencer Wells' forceps on the eleventh day on one side and on the thirteenth day on the other; the elastic ligature came away with the pedicle on the nineteenth day, leaving a large funnel-shaped opening, covered with healthy granulations. There was never any suppuration from the pedicle, it becoming dry and mummified, but on the twelfth day a small fecal fistula formed on the side of the pedicle, discharging small quantities of fecal matter at first, which ceased, however, after about ten days, nothing but some flatus coming from it now occasionally. Abdominal incision was healed by first intention when sutures were removed on tenth day.

There is now, eight weeks after the operation, only a small granulating surface left at the seat of the pedicle, not larger than a five-cent piece, which is rapidly cicatrizing. The patient has gained flesh since the operation, and feels perfectly well, so that she will be able to leave for her home in Ohio in a few days.

The tumor weighed twenty-six pounds, not including the pieces cut away in trimming the pedicle; they, in connection with the blood lost during the operation, would have probably increased its weight to forty pounds. The tumor was a fibro-cyst, but contained large cystic cavities; it presented rather an œdematous, spongy condition. Even when lying on the table distinct fluctuation could be obtained, and on its cut surface small drops of serous fluid were observed, like drops of sweat. No microscopical examination of the tumor was made; I had intended to harden it in alcohol and preserve it, but the weather was intensely hot, and it spoiled in a few days.

The interesting points of this case are: 1, the youth of the patient; tumors of this kind are rarely found at a less age than thirty-five; 2, the rapidity of its growth; it attained this enormous size in eight months, without causing much local or constitutional disturbance; 3, its distinct increase in size always two weeks after each menstruation; periodical enlargement of fibroid tumors is not uncommon, but this occurs generally during menstruation. The question naturally suggests itself whether swelling of the growth in this case did not correspond to the time of ovulation.

That a diagnosis of ovarian cyst was made in this case is not surprising. The fact is that it is impossible to differentiate fibro-cystic tumors of the uterus, especially when of such large size as this, from ovarian tumors, as all the physical signs are almost identical. Gusserow, in his book on fibroids of the uterus, "Encycop. Obstetrics and Gynæcology," says: "The diagnosis of these tumors has only been made in the most exceptional cases, and even then has been the result of accident rather than of correct appreciation of the symptoms. Fibro-cysts so closely resemble multilocular ovarian cysts, particularly in their location and in their fluctuation, that the frequency with which they have been mistaken for ovarian tumors is not astonishing."

BRIGHT'S DISEASE WITHOUT URINARY SYMPTOMS.

By W. W. KNIGHT, M.D.
Pathologist to Hartford Hospital, Hartford, Conn.

THE physiological function of the kidneys would seem to be a comparatively simple one; mainly the excretion of urea with a small amount of other excrementitious matters, all being held in solution in a suitable amount of water. But when the kidneys become diseased and their function hindered or suppressed, we observe a variability in the resulting symptoms which hardly occurs in disease of any other organ.

The term Bright's disease includes several different pathological processes, but even where the disease process is apparently precisely the same, the systemic effect is manifested by a great diversity of symptoms. In some cases dropsy is the prominent symptom, in others it does not occur at all, in some cases convulsions or coma, in others sometimes headache, or eye troubles or dyspnœa, etc., none of them pathognomonic, and frequently all conspicuous only by their absence. In consequence of this variability we depend upon the urinary symptoms for a positive diagnosis. We look for changes in the amount and specific gravity of the urine, for albumen and casts, and finding them we are sure of our diagnosis. Their temporary absence is well known to be of not infrequent occurrence in cases of nephritis, but if after several examinations we find none of these urinary symptoms, the most careful of us ordinarily feel justified in excluding Bright's disease, and of course in the great majority of cases we make no mistake; but post-mortem examinations occasionally show that we do have cases of Bright's disease which run their course without at any time anything abnormal in the water being shown by more than ordinarily careful urinary examination. While our authorities all speak of the temporary absence of urinary symptoms, the only one I have seen who refers to their persistent absence is Porter, and he merely refers to it casually as one of the possibilities in this disease. So little is written on this point, and so seldom is it referred to, that it has seemed to me worth while bringing it before this Society for discussion, by the relation of two cases in which an autopsy showed the existence of nephritis, but where frequent examinations of the water for some time before death, failed to detect anything abnormal; no albumen, no casts, specific gravity normal and the amount in due proportion to the amount of fluid ingested.

CASE I.—Was that of a woman whom I was called to see December 15th, 1888. She had been taken

sick in the preceding September, with inflammatory rheumatism. Under homœopathic treatment, this ran its usual course of five or six weeks During this time there had been little actual vomiting, but considerable nausea and inability to take food. After the subsidence of the inflammatory symptoms the patient did not recover strength and was still confined to her bed. She continued in this condition with no prominent symptoms except loss of strength and flesh, until about the first of December, when persistent vomiting became a marked symptom, and after a little the vomited matter became bloody. During this time the water was frequently tested for albumen, but none found. It was somewhat scanty and at times of rather low specific gravity, but never persistently low and the amount as much as would be expected in a person taking as little nourishment. When I visited her I found persistent vomiting, the ejected matters frequently containing blood. The patient was much emaciated; pulse and temperature normal, no symptoms of any brain trouble. The hematemesis of course led to suspicion of gastric cancer, but no tumor could be detected, neither was there the severe pain indicative of cancer. In short, there were no symptoms except the gastric ones, and the great weakness that would naturally follow upon an almost complete inability to take food for three months. During the last ten weeks of this time she had been nourished solely by enemata of beef tea.

A specimen of the water showed a specific gravity of 1020, contained no albumen and no casts. Subsequent specimens gave the same results. After a few days the vomiting lessened and the hematemesis stopped, but the patient died of pure exhaustion, December 25th, 1888.

At the post-mortem examination, nothing was found abnormal in the stomach except a slight congestion. The heart was slightly hypertrophied, the kidneys were a little smaller than normal, dark red in color, firm in texture, capsule easily removed, but tearing slightly the surface of the kidney, which was slightly granular, cortical portion diminished in size, striations indistinct. These changes thus indicate typically the contracting stage of a chronic interstitial nephritis. The brain was not examined.

Case II.—Was that of a patient of Dr. Storrs, to whom I am indebted for the following ante-mortem history: Male, aged 62, first seen in June, 1887; was called on account of vomiting. The patient was pale, sallow, and anæmic; had not felt quite up to usual condition for some time previous, but had not been sick enough to consult a physician. There were no symptoms aside from the vomiting, which was obstinate. The urine was examined, with negative results; no albumen, no casts, specific gravity 1018; the amount about two pints, as much as would be expected where the stomach was retaining so little. After a time there was some improvement, and the patient spent the summer at different health resorts, but was subject to frequent attacks of vomiting. At no time was there dropsy or any other symptom of Bright's disease. During the winter the vomiting became more troublesome, and the patient died of simple exhaustion in March, 1888. During these nine months the water was frequently examined, both chemically and microscopically, and at no time was the least abnormality detected. At the request of Dr. Storrs I made an autopsy with the following results: Body fairly well nourished; heart, lungs and stomach normal; no hypertrophy of the heart; the kidneys were enlarged, capsule easily removed, surface smooth, cortical portion increased, light colored, presenting all the appearances of the second stage of chronic interstitial nephritis, commonly called "large white kidney."

It is unnecessary to relate in detail two other autopsies I have made to determine the cause of death resulting from persistent vomiting, and found that the cause was Bright's disease. The urine in these cases had been frequently examined for some time previous to death, with negative results.

These four cases are illustrations of that class to which I wish to call your attention, and they seem, too, not to be so very uncommon. It would be idle to deny that albumen and casts might have been found at some time in the course of the disease in these cases, but the water was examined much more frequently than we ordinarily do such work, so that for diagnostic purposes, at least, they may fairly be called cases of Bright's disease, running their course without urinary symptoms. Case II is especially interesting, in that it presented the large white kidney, a form of Bright's disease in which we are most certain to get a large amount of albumen. None of these were cases of true cirrhotic kidney, where we get a large amount of water of a low specific gravity, with little, and frequently no, albumen.

Just how to explain a case of Bright's disease, running its course without the appearance of albumen and casts in the water, is a difficult matter. The explanation usually given by writers, of the temporary absence of these symptoms, namely: that the diseased tubules are so completely plugged with casts that no urine is secreted by those tubules, and so no albumen and casts can reach the water, may, possibly, apply to these cases.

All of the cases to which I have referred were cases of protracted vomiting. We would be hardly justified in concluding from this that these are the only cases in which there is absence of albumen and casts. Such cases become prominent, because we are more apt to get a post mortem examination in such cases, by reason of the persistent vomiting being such a prominent symptom. I think it very probable that some other fatal cases of obscure troubles are cases of Bright's disease without albumen or casts in the water. I have never made an autopsy in such a case, but I have seen deaths from convulsions, for example, where nothing was found wrong with the water, but where it seemed as if nothing else than Bright's disease could be the cause of the symptoms.

The immediate cause of the symptoms, especially the vomiting, in such cases as have been related, is obscure. The post-mortem examination showed no local trouble with the stomach, and the peculiar character of the vomiting is indicative of the constant action on the nerve centers of some chemical toxic substance. In common parlance we call this condition

uræmia, but no one at the present day believes that it is due simply to the retention in the blood of urea, and in the cases related the amount and specific gravity of the urine indicate, when we consider the amount of food retained, the elimination of a proper amount of urea. When the true explanation does come, it will very likely locate the trouble somewhere in that complex series of changes by which the nitrogenous elements of the body are converted into urea and uric acid. Preceding or accompanying the formation of these final substances, there are produced numerous little known alkaloids named leucomaines, some of them poisonous, others requiring little chemical change to render them toxic. Under normal conditions we either excrete or further oxidize these toxic bodies into harmless substances, but in Bright's disease we may suppose that this metabolic process is interfered with in some way, so that some poisonous alkaloid accumulates in the system in quantity sufficient to cause the symptoms we call uræmia. If we put the cause here, we can see why our ordinary eliminative treatment, especially in these cases where apparently a normal amount of solid material is excreted, is of so little benefit, and I think you will all agree that these vomiting cases are most difficult to benefit.

In regard to the diagnosis of these cases, it is not easy to be positive. Here the practically pathognomonic symptoms of albumen and casts fail, as we must depend on the general appearance of the case, and especially upon the exclusion of other diseases. To a certain extent, the character of the vomiting is diagnostic. It would be difficult to mention another disease in which such continuous and persistent vomiting, nausea and retching stand alone as the prominent symptoms. The patient gets no relief; vomits whenever anything is taken into the stomach, or when a little mucus accumulates there. During all this there is not the pain of gastric ulcer, nor the pain and tumor of cancer. Hematemesis is not common, but does sometimes occur, as in case I. In sixty-eight cases of chronic Bright's disease, described by Dickinson, it was present in only three. By excluding other causes, and paying attention to the character of the vomiting, we shall be able, in many cases, to make at least a probable diagnosis.

Allied to these cases of complete absence of albumen and casts, are those cases where these symptoms are temporarily absent. This is well illustrated by a case now under my charge. I was called to see a woman on account of vomiting. There was no œdema, no brain symptoms, in fact, nothing except the vomiting. I examined a specimen of the water and found it normal. The vomiting persisting, two days later I examined another specimen and found an abundance of albumen and casts; two days later another specimen showed no albumen, and only a few casts. Such cases are common, and are referred to only for the purpose of calling attention to the necessity of making several examinations of the urine, in doubtful cases. The results of post-mortem examinations have shown me that this necessity is sometimes overlooked.

There is another class of cases where renal complications are apt to pass unnoticed. This includes those people, especially elderly persons, whose kidneys perhaps cannot be called diseased, but in whom these organs are, during health, worked to their full capacity in order to excrete all effete material. In this condition, when some acute disease comes, and sometimes only a very slight trouble, the kidneys are unable to do the extra work required in eliminating the increased amount of excrementitious materials, and an acute parenchymatous nephritis is set up, which becomes an important factor in the case. Unless the water is thoroughly examined, these persons seem to die from very slight causes.

I have brought forward this subject, not for the purpose of saying anything new or original, but because the making of post-mortem examinations had shown me that Bright's disease is frequently overlooked, sometimes no examination of the water had been made, sometimes because only one specimen had been examined, and sometimes in those more rare and more excusable cases where there had been no urinary symptoms.

Hydrotherapeutics.

By S. BARUCH, M.D.,
Attending Physician New York Juvenile Asylum and Manhattan General Hospital.

Omission.—In describing the technique of Brand's method in the last article, a serious omission occurred which I desire to rectify. During the continuance of the bath, a pitcher or basinful of the bath water should be gently poured upon the patient's head and allowed to flow over his neck and shoulders while he is held in a half-sitting posture. To prevent the water running over the face, which is unpleasant, a napkin or large handkerchief should be made into a bandage after folding it into a triangle. The middle portion passing over the forehead, the ends are tied upon the nucha, forming a trough, as it were, which leads the water poured upon the head down upon the neck and shoulders. This gentle affusion should be repeated twice during the bath. As the patient emerges from the bath a large basinful of colder water should be poured over his shoulders for the stimulating effect, which aids in producing reaction.

These affusions are an important element of the Brand bath, and should never be omitted.

VI.

QUERIES AND OBJECTIONS ANSWERED.

CONTRA-INDICATIONS CONSIDERED.

THE intelligent student of the cold-bath treatment of typhoid fever, finds himself perplexed by many questions which imperatively demand solution, when he is called upon to make an actual clinical demonstration at the bedside.

To forestall these difficulties, which the reader will surely encounter, and enable him to overcome them, I propose to discuss several queries and objections, which correspondence, personal experience and discussion have brought to my attention.

Is the rule to bathe every three hours in winter, at 65° F., whenever the temperature reaches 103° F., absolute, and not to be modified to adapt it to each case? Most assuredly, I would never deviate from the rule, with one exception (noted below), because this rule has been established by deduction from large clinical material, carefully gathered by numerous observers in different localities in private, hospital, and in military practice. It must always be borne in mind, too, that the object of the bath is prophylactic; its aim is not a mere reduction of temperature, but a suppression of the violence of the febrile movement until it has spent its force.

Whoever expects to throttle the fever by the bath will surely be disappointed, for its course is as steady and inexorable as any law of nature. The temperature will almost invariably fall from one to three degrees after each bath, only, however, to rise again to within a fraction of its former rate when the three-hourly examination is made. But from day to day there will be a gradual, yet steadfast diminution of the *average temperature*, which indicates that the resisting power of the system is gaining sway over the disease. This is the usual effect of the systematic cold bath, administered without fear and without favor. Whenever we attempt to substitute another form of hydriatic procedure, to raise the temperature of the bath water, to shorten the duration of the bath, or otherwise to change the rule, we must expect a change in the result. If the case comes under treatment late, the resisting power of the disease will be greater, hence the result of the bath will deviate from that here depicted. The type of severity of the disease, too, will exert its influence upon the latter. If the temperature fails to be favorably influenced by the systematic baths at 65°, a lower temperature, not below 60°, will be found useful in the first two weeks of the disease. Occurring later, a persistently high temperature will probably be due to complications, in the prevention of which the systematic cold bath has far more influence than in their treatment. One point should be ever present in the mind of the attendant—viz., the chief aim of the cold bath is to endow the system with power to resist the disease; hence it is all important to begin it early, and not to expect so much (though still a considerable effect) from it, when the disease has already made decided inroads upon the blood and the vital organs.

One correspondent has said that "this is a very delicate adjustment of treatment, when a patient is saved or doomed, according as it is inagurated on the fourth or fifth day." As I have elsewhere said, this objection, if valid, would apply to much of our therapeutic endeavor. *Obsta principiis* is the first principle of rational therapeutics. Disease has often been likened to a conflagration, the ease of whose subdual is in proportion to the stage at which it is attacked. In the severe types of malarial fever, for instance, one day's—yes, even one hour's—cinchonization may save the patient's life; its delay doom him to death, or to a long-continued invalidism. Brand has demonstrated as clearly as anything can be demonstrated by clinical data, not from his own practice only, but from that of others also, that *out of two thousand cases treated before the fifth day not one died.* The uncertainty of diagnosis here steps in to mar possible success. Before the appearance of the spots, we cannot pronounce definitely whether we have a case of typhoid fever, acute tuberculosis, gastric fever, pneumonia, acute nephritis, or one of the exanthemata. We have the satisfaction of realizing, however, that in the large proportion of cases these diseases may readily be excluded. But we may escape from the dilemma entirely if we adopt the rule laid down in the early portion of this series, to subject every case of fever whose temperature persistently marks as above 103°, for several hours, to cold bathing in a mild form. Experience has taught that no harm will ensue from such a course. The systematic bath may aid us in reaching a diagnosis. In acute tuberculosis, for instance, the symptoms will not be ameliorated as in typhoid, and even if the bath were capable of damaging the patient's prospects, the latter cannot be done, because the disease is invariably fatal. In the low forms of the initial stage of some of the exanthemata, with high temperature, cold affusions have been found so effective by Currie, and later by Ziemssen and others, that a few ablutions or baths will surely not damage the patient's chances, but rather rescue him from the ataxic condition and save his life.

All cases of typhoid fever should be subjected to the bath. One correspondent asks "if a patient has a temperature of 104° for an hour or two every evening, but with moderate fever for the rest of the time, and without "Functionsstoerung," should you then think it necessary to insist upon the bath? This is a question that will frequently arise in the mind of the practitioner, who would fain shrink from the trouble, annoyance and possible criticism of the bath procedures, so long as the case presents a mild aspect. It will not be difficult for the attendant to order and insist upon the cold bath, if the patient has a temperature of 105°, with delirium, stupor, but when he appears to be comfortable, with a temperature ranging from 102° to 103°, or 104°, it does seem so glaring a violation of the long-established expectant treatment, to disturb his comfort by a cold bath, that few men will have the temerity to advise it. The experienced practitioner, however, knows, but too well, how sadly his prognosis, derived from an early, mild course, sometimes fails to be verified, when, in the beginning of the third week, the first sound of the heart begins to fail, the pulse becomes rapid, the lung becomes hypostatic, hemorrhage, perforation, and death close the scene. We rarely witness the death of a case of typhoid in the first week from excessive temperature or from failure of the nervous system; the chief danger lies in the infective process, which undermines the system slowly but surely. To meet this danger, the cold bath is our shield and ever-ready weapon. In mild cases, the rise of temperature and pulse are readily combated by it; the resisting power of the disease is feeble. Hence the temperature rises only at long intervals to 103° F., but *whenever it does so rise, the rule should be inexorable;* the bath must be administered. Clinical ex-

perience demands it, and if we would receive its benefits we must obey the behest.

Is there not danger of producing lung complications by cold bathing? This question has also been abundantly answered by clinical demonstration. There can be no more threatening conditions than exist in the military hospital of Vogl, in Munich. If a combination of cold air and very cold baths do not produce bronchitis, pneumonia and pleurisy in typhoid fever, the bath alone may be regarded as free from such accusation. Vogl places his infectious cases in barracks, which are built of wood, as summer pavilions, resting upon pillars, which support a double floor, whose ventilation is complete; the roof, ceiling and walls are also arranged for perfect circulation of air.

During the severest part of the winter he closes the open spaces under the roof and between the floors by simple boarding up, and starts a fire in the cast-iron stoves, *all the windows remain open*, unless strong winds, rain or snowdrift forbid, which the neighboring buildings somewhat prevent. The patient is only protected against direct drafts of cold air; the windows adjoining the tubs are always closed. As the entire length of the barracks consists of windows, without intervening walls, the patients pratically lie in the open air. "In severe weather we rarely can raise the temperature above o C. (32° F.). The fear of cold and circulating air is unjustified. I am so accustomed to hear from my visitors expressions of apprehension on the point, that I do not wonder if the reader feels the same. Just as I have convinced the former, so I hope to convince the latter, that a thorough lung ventilation protects against adhesive processes; the cooling effect of the cold air and increase thereby of heat dissipation from the whole body, forms together with the baths the basis for our success. An experience of ten years' conscientious observation without prejudice is surely entitled to consideration. I have never heard complaints nor experienced anything but benefit from the extensive and thorough ventilation of our barracks, and I feel that I have not departed from the useful. Bronchial catarrh, angina, are just as rare here as in the large wards; we have never seen severe erysipelas. A very anæmic, pleuritic patient, who was sent to the barracks with a sub-febrile temperature, was transferred into the large ward when cold weather commenced. His temperature rose at once and remained high for five days, with strong morning remission. The high temperature ceased at once on his being returned to the barracks. The unpleasant effect upon the anæmic patient, but not upon the accompanying bronchitis, drove him back to the ward, where his temperature again rose, so that he asked to be transferred to the barrack, where he recovered. There was not a single death from pneumonia or bronchitis, and only one from pleurisy, in cases treated by strictly cold bathing and this open-air method. I could cite much other striking testimony on this point, but none more convincing, I trust."

On the contrary, so far from producing lung complications, the numerous cases detailed in extenso by Brand, and by Tripier and Bouveret and others, go to prove that we have in the cold bath the most effective treatment of these complications, when they occur *during* typhoid fever. Only when they occur in far advanced stages of the fever with great adynamia, the cold bath should be exchanged for that of a milder temperature and more brief duration.

Many complications arising in the course of the disease may cause the practitioner to pause in the strict pursuit of the cold bath treatment. The work of Tripier and Bouveret refers to these in extenso, entering upon the discussion of each so minutely that it is a mine of information from which I draw on this subject, because there exists no English translation.

Nose-bleed is not a contraindication; even in severe cases it usually ceases after bathing. Hæmoptysis is so rare that it occurred only eleven times in five thousand cases. If it occurs in an advanced stage of the disease, or with cyanosis and pronounced heart feebleness, it is well to desist from cold baths, even if there be a high temperature and severe cerebral symptoms, which is a rare occurrence.

In the early stages a bloody or streaked expectoration does not forbid the bath.

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL.

PULSATING BRONCHOCELE.

WAUGH presented at his clinic a case of pulsating bronchocele. The left lobe was much larger than the right. The upper central part presented a heaving pulsation, a thrill, and a bruit heard on auscultation, which he described as typical of the signs of aneurism. They came, however, from a part of the goitrous mass, which rose upon the patient's swallowing; and there were none of the pressure symptoms of aneurism present. The lecturer stated that there was probably a dilated condition of the arteries present; probably an anastomotic aneurism of this portion of the gland. He recommended the use of iodine internally and externally, and the inunction of an ointment of biniodide of mercury in lanoline; to be applied twice a week, the patient to expose the neck to the rays of the sun for an hour afterwards. The condition of the bloodvessels rendered the use of coagulating injections dangerous, while removal of the tumor would probably be followed by the occurrence of myxœdema. He considered the safest treatment to be that he then prescribed.

MT. SINAI HOSPITAL, NEW YORK.

PARAMETRITIC ABSCESS AND INCISION.

IN this case of parametritic abscess, I call your attention to its large size, its high situation in the iliac fossa extending nearly up to the lower ribs, and to the fact that it cannot be felt from the vagina.

The treatment is very simple. Incision; a drainage-tube will be inserted, the cavity irrigated with an antiseptic solution; in a few days the tube will be removed, and the cavity packed with iodoform gauze; left to heal by granulation.

LAYING OF THE CORNER STONE OF THE NEW YORK ACADEMY OF MEDICINE.

WEDNESDAY afternoon, the 2d inst., was a red letter day in the medical history of New York. The ceremony of laying the corner stone of the New York Academy of Medicine, attracted a large audience to West 43d street, near Fifth avenue. A platform, erected upon the sidewalk and a portion of the street, was occupied by representative members of the profession, among whom were a fair sprinkling of the gentle sex. Within the foundation limits of the building another platform contained the President and Ex-Presidents of the New York Academy of Medicine, and of other local societies, besides Ex-President Cleveland, Bishop Potter, and the Rev. Dr. John Hall. Among the audience were noticed Mr. J. H. Schiff and a number of other philanthropic gentlemen, who are ever foremost in all good deeds.

Dr. Loomis introduced Bishop Potter, who offered a fervent invocation. He was followed by Dr. A. Jacobi, whose address recounted the struggles and aims of the New York Academy of Medicine in fitting terms, and made a manly appeal for support of an institution to which the lay public owes much more than the physician. He dwelt upon the great importance of thorough education of physicians, and urged laymen to be wary in their selection of medical attendants. The latter, he said, should not be chosen because he is an agreeable companion in the theatre or club, but with a view to his capacity for protecting the family against disease. The address was couched in that earnest and sound language and diction; which is the characteristic of Dr. Jacobi's utterances. It cannot fail to impress the public with a due sense of its interest in the erection and maintenance of the new academy.

Ex-President Cleveland made a favorable impression by his remarks, whose text was the importance of aiding in the maintenance of the free institutions, to the existence of which we owe the possibility of erecting such shrines to Science. He said that physicians do not discharge their full duty by their devotion to their science alone, but that it is incumbent upon them also to give to political topics and movements the benefit of their trained thought and well-informed judgment. In this way alone, he claimed, the foundations upon which professional success rests, may be rendered secure. He hoped that, when the discovery of our continent shall be celebrated in this city two years hence, the completed academy building may be pointed out as a splendid monument of the progress of our medical education.

The corner-stone, upon which "N. Y. A. M., 1847–1889," is cut, was placed in position by Dr. Loomis, together with a box containing the documents relating to the academy. The new building will be a substantial but modest piece of architecture, five stories high, of modified Romanesque type. Its front will be of fine grained red sandstone and brick. Beside the large "Hosack Hall" (named in memory of Dr. Alex. Hosack, whose widow gave the academy $70,000), whose dimensions will be 28 x 31 feet, and another hall of 42 x 57 feet, there will be some thirty-five other smaller rooms, and a number for the meeting of the sections. The library will have a capacity for 250,000 volumes. There is a prospect of having the building completed in a year. We wish the New York Academy of Medicine, whose discussions have added vastly to the progress of medical science, God speed.

MEDICAL ORATORY.

ONE of the reasons why students become drowsy and find it difficult to give continued attention to lectures is, as we have intimated in a previous editorial, that the brain and circulation have become sluggish in their actions from insufficient fresh air and outdoor exercise. But there is another explanation more forcible still—namely, the sluggish manner in which many lecturers deliver what they have to say. It is the same with speakers as with writers:

> Un style trop égal et toujours uniforme
> En vain brille á nos yeux, il faut qu'il nous endorme.

Once we enjoyed listening to a spirited debate upon the question of oratory in the pulpit. One side maintained that divine truth itself was quite sufficient to rivet the attention of any thinking audience, when presented without oratorical ornamentation. The other side simply rested upon the stronger argument of facts, and had but to apply the *argumentum ad hominam* in asking their opponents if they never felt the leaden weight of their eyelids grow weightier during a sermon in which there was neither gesticulation nor eloquence. Of course, the latter side won; but in regard to the delivery of medical lectures, arguments similar to those of the former debaters are continually being advanced and most strenuously, we

fear, by those who are defective themselves in the art of graceful speaking.

Eloquence of the best sort consists of the use of plain and refined language, impressive and pleasing modulations of the voice, the employment of apt and terse illustrations, and the use of appropriate gesticulations harmonizing with the thoughts expressed. Mere florid imagery and hyperbole of speech is but a debased form of oratory and the refuge of ambitious weaklings. It has no place either upon the public platform or in the halls of science.

Undoubtedly, the best means of imparting simple knowledge is the laboratory and the work-room, but since the didactic lecture still remains, and for certain reasons is likely to remain a part at least of collegiate methods of teaching, it should be made more beneficial by the use of style in its presentation. Many of our finest instructors upon medical subjects have been those who would say what they had to impart in a way that fixed the attention of every student. However dull or indifferent the latter might be, the charm and force of the speaker's manner compelled him to listen and to receive the knowledge being offered. What a treat it is to listen to a man who, perfectly acquainted with and enthusiastic about the subject of his lecture, makes it glow and burn into the minds of his hearers by reason of his well-chosen words, impassioned manner, and clear illustrations. We are positive that much of the opprobrium that has been cast upon the didactic lecture as a mode of teaching has been caused by the stale, sleepy, halting, and indifferent way that most of them are delivered. A man may be a master in the laboratory and a mere dead weight in the lecture-room, his aptitude should place him where he belongs for the best interests of medical teaching. Unfamiliarity with the subject is not unfrequently the cause of bad lectures, for,

> Ce que l'on concoit bien s'enonce clairement,
> Et les mots pour le dire arrivent aisément.

In commenting upon a recent editorial upon this same question in the New York *Medical Record*, Dr. Roberts even goes so far as to say that no student ought to be compelled to attend lectures of this stupid sort, particularly when they are simply the reading of that which might be quite as well obtained from any ordinary text-book. He thinks if such a leniency were granted the student, it would act as a wholesome stimulant to lecturers for the improvement of their powers of delivery.

As the best means of teaching scientific subjects, we only favor the didactic lecture in a certain few particulars, as, for instance, when they are to be illustrated by experiments before large classes, and when they contain particularly original ideas, the result of individual experience and study. But we do maintain that among medical teachers there is a positive need of more eloquence, or rather, graceful style of speaking. What a noble opportunity is afforded for it, in the picturing of disease, in portraying the various symptoms, in illustrating the effects of drugs, in developing the history of maladies and epidemics, in exhibiting by cumulative arguments the attainment of certain great medical facts, in demonstrating the wonders of the human body, in showing its marvellous activities in life, and in impressing the dangers and advantages of surgery? Some of the dullest subjects in the medical curriculum have been made the most attractive, some of the minutest details have been raised to their merited importance, and some of the most difficult problems have been rendered the easiest, by the employment of so simple a means as a better style of delivery in the lecture. Above all, the scientific lecturers should take heed of the advice of Horace when he says:

> Quidquid præcipies, esto brevis, ut cito dicta
> Percipiant animi dociles, teneantque fideles.

Brevity and eloquence will make any lecture, however dull the subject of it may be, a thing to be enjoyed, and consequently to be remembered.

CO-EDUCATION IN MEDICINE.

THE announcement was made last week that the University of Pennsylvania contemplated throwing open her classes for the admission of women. No exceptions were mentioned, and the wording of the resolution, which was passed by the Faculty with but two dissenting votes, warrants the inference that the school of medicine was included.

As to the other departments, the action is only to be blamed on account of its lateness. The University cannot claim the honor of the pioneer in this matter, as many reputable schools have for years admitted women to their privileges, and the ability of the fair sex to cope with the male students, in the college classes and in the subsequent battle of life, has been fully demonstrated. With every movement looking towards the emancipation of woman, and giving her the opportunity to fit herself for any position she has the ambition to aim for, we have the heartiest sympathy. If she wishes to be a designer, an artist, an engineer, or a doctor, then, in the name of that liberty for which our fathers fought, throw open to her the doors of the schools, and allow her every opportunity and privilege which the male student enjoys.

In many respects, also, we approve of the system of co-education of the sexes. The advantages to both have been so fully discussed that we need only stop to allude to them here. Competition is stimulated and courtesy developed by the presence of both sexes in the same class. The sentiment of those who have taught mixed classes is practically unanimous in its favor. In fact, so many schools have admitted women to their classes, that it is doubtful whether the action of the University is most notable as an advance in the matter of female emancipation, or as an illustration of Philadelphia conservatism.

In the department of medicine, it appears to us

that the women have come to stay. They have surmounted every obstacle, overcome the most deeply rooted prejudice, and their success in the field of practice has demonstrated their fitness. The work of Mary Putnam Jacobi is alone a full justification of the claim of women to enter the medical profession.

But in this study we cannot approve of co-education. We cannot but believe that this would tend to weaken the barriers of delicacy, and create a degree of familiarity which is not conducive to morality. Men are men, women are women, and the fact that both are engaged in the high and noble study of the art of healing by no means frees them from the instincts of their animal nature. The study of the problems of physiology and pathology might possess too vivid an interest under such circumstances. Nor is there any necessity for such co-education. We have in Philadelphia a well equipped school for women, which affords all requisite facilities for the study of medicine; and if any further opportunities were needed, it should be by the opening of another school for women rather than admitting them to the classes with men. The impulses which would lead the students of either sex to prefer to enter a school with mixed classes are precisely those which would render such association most objectionable.

Annotations.

ACCORDING to Merck's *Bulletin*, amylene hydrate, an excellent hypnotic, is devoid of accessory or subsequent symptoms, when it is of a very high degree of purity. Having a formula $C_5H_{12}O$, it is a very mobile, colorless liquid, of specific gravity 0.81, and boiling point 100° C. (212° F.). It is soluble, *when pure*, in eight parts of water, and may be mixed with alcohol in all proportions. It has an ethereo-camphoraceous taste, followed with a peppermint-like after-sensation. After an extensive experimentation, von Mering (*Therapeutische Monatshefte*, July) gives as its physiological action a perfect hypnotic effect, resembling natural sleep, without any alteration of the heart-frequency and blood-pressure. In medium doses it affects principally the cerebrum; in excessive doses it acts upon the spinal cord and medulla, and causes a disappearance of the reflex actions, cessation of respiration and an arrest of the heart. It is principally used in cases of nervous wakefulness, and occupies a place intermediate between chloral hydrate and paraldehyde. It is best administered by mouth or by rectum. The following is the most recent formula recommended by von Mering for its administration:

℞.—Amylene hydrate . . . . . ℈vss.
Orange-flower water . . . . . ʒj, ʒv.
Syrup of bitter orange-peel . . . ʒj.
Take *one-half* at bed-time.

An easy mode of giving it is to stir a teaspoonful of simple amylene hydrate with a wineglassful of beer for several minutes; then drink the mixture, and follow it by a mouthful of beer alone. Sometimes sugar may be added. Capsules containing 15 grains may be followed by a mouthful of water, beer, or wine each. Congestion, headaches, nauseas, and vomitings, are liable to be engendered by impure brands of the drug.

IN a paper on the Non-Retention of Urine by Young Girls and Women, by H. Marion Sims, in the *American Journal of Obstetrics*, for September, 1889, this troublesome condition is attributed to the contraction of the walls of the bladder due to the hypertrophy of the muscular coat and the consequent loss of its holding capacity.

He has treated a number of cases in both children and adults, and has had the satisfaction of curing all but two of the cases completely, with no other aid than forcible dilatation by warm water. This was done by using an ordinary silver catheter, to which was attached a Davidson syringe. The quantity of water injected was measured by knowing that the bulb of the syringe, when completely emptied, threw into the bladder exactly one ounce of water. The water used was just comfortably warm. In one of these cases the bladder would hold at the first time but one and three quarter ounces, and the quantity was increased gradually each day, until it would hold eighteen ounces of water, and that without severe pain. The treatment lasted three months.

BY means of our ready facilities for research, we are enabled to call attention to an oversight, and credit the proper authorities with the method for collecting bacteria and other microörganisms in drinking water, for biological examination and analysis, described on page 695 of the September number of the *University Medical Magazine*. The use of sterilized asbestos in glass tubes, as there suggested by Prof. Dixon, was recommended some three years ago by Petri, chief-assistant to Prof. Koch in Berlin, with a full account of the same in the *Zeitschrift Für Hygiene*. The method has been employed ever since in the regular examination of the water supplied to the city of Berlin.

Letters to the Editor.

ANTIFEBRIN.

IN reply to Dr. Saylor on "antifebrin" in your issue of September 7, I would say that a temperature of 102 to 103 in a child, is not of sufficient magnitude to cause much anxiety, nor would it be even in an adult; though I can see no fault in an administration of antipyretics to a moderate degree. The Doctor states that authorities claim that the effect of the drug lasts six hours, and asks if I would not commit the same error as Dr. Penny, if I repeated the dose every three or four hours. I think I stated that I repeated the dose every three or four hours until I got the desired effects, and, inasmuch as the drug manifests its effects in from thirty to sixty minutes, there would hardly be any danger in giving the drug as I suggested.

SUPPOSED NEURALGIA.

MR. H—, age twenty-three, who had been suffering from neuralgia on the left side of the face, for the last two years, called on me for treatment, and gave the following history: Two years ago in July, he had been troubled with an abscessed tooth, and had the same extracted; the pain had ceased for about a week, but came on again, and he has had it since, periodically, it being more severe in damp weather, but never leaving him for more than a few days at a time. He had taken all kinds of drugs, but did not get much relief from them, and finally called on me, suggesting that he thought the pain was caused by a wisdom tooth next to the space of the extracted molar. I examined the same and found it, as well as the surrounding tissue, in a healthy condition. That it might be a lesion of the floor of the antrum next suggested itself to me; I therefore opened up the gum freely and immediately upon my doing so the pus began to flow; I cleaned it out thoroughly, and upon probing into the cavity, I struck a hard substance, which upon removal proved to be one of the roots of the extracted abscessed tooth. It was lying horizontally in the gum and was pressing against the floor of the antrum. After removing the root and pus from the cavity, I thoroughly antiseptic ized it. It healed very nicely, and the patient has been free from pain ever since. As a local anæsthetic in this operation I used:

℞.—Olei cinnamomi . . . . . ʒj.
Olei gaultheriæ . . . . . ʒiij.
Acidi carbolici . . . . . ʒij.
M.—Applied until the part turns white.

I have used the same in tooth extractions and other minor operations with general success.

DR. W. U. ROSENTHAL.

CHICAGO, ILL.

DOUBLE AMPUTATION OF THE FEET.

THE patient, forty-four years old, a man of dissipated habits, had been guilty of a misdemeanor and in order to evade arrest, had slept out of doors in a straw stack during a very cold night, freezing all of his toes as well as the contiguous parts of his feet so severely as to require amputation. When I first saw him his toes were black, dry, and could have been disarticulated by slight torsion. Immediately above the metatarso-phalangeal articulations of both feet a line of demarcation was quite apparent with a very free and offensive discharge of pus, coming mostly from the joints. After putting the patient under the influence of an anæsthetic, I amputated one foot through the tarsus so as to remove the navicular and cuboid bones with all of the parts in front, according to Chopart's method, procuring a good flap from the sole of the foot. Dr. C. McCracken, of this place, who was assisting, amputated the other in the same way with same results. By the time the stumps were dressed, the patient had rallied from the anæsthetic and shock without any of the unpleasant effects which often follow operations. Local treatment consisted of sol. hyd. corros. 1 to 1000 used as a spray at each dressing. As an ointment for dressing:

℞—Cerati resinæ,
Copaibæ . . . . . partes equales
Fiat unguentum.
Sig. To be used pro re nata.

The stumps healed rapidly, and in a few weeks the patient was able to be around on crutches and shortly after went to work, his trade being that of a cooper. When I last heard from him, one year after the operation, he could walk very well, and his lameness did not prevent him from doing a full day's work.

T. G. STEPHENS, M.D.

Society Notes.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Special Meeting, August 20th, 1889.

JAMES MCCANN, M.D., IN THE CHAIR.

TREATMENT OF PULMONARY PHTHISIS.

DR. LANGE reported a new method for the treatment of pulmonary phthisis. "The method consists in the inhalation of vaporized mercury and iodine. Of the results of this method I have nothing to say. I cannot forget that grass has not yet grown upon the grave of gaseous enemata, and I am aware that many men, many years and many cases, are required to produce evidence of the usefulness of any remedy or method in the treatment of anything, even when the remedy or method possesses usefulness. I report this method because I desire co-workers.

It suggested itself to me that vaporized mercury, if brought into more or less direct contact with the bacillus of Koch, might destroy it, and that iodine, if applied directly to the ulcerating surfaces of lung tissue might effect a more powerful beneficial action than that resulting from its ordinary method of administration. I have had, and still have, the valuable assistance of Dr. Tingley in the preparation of apparatus and in devising ways and means by which these vapors may be satisfactorily administered to patients. This has presented many difficulties. A principal one is, that I know of no manner, as yet, by which a definite, a known quantity, can be given. The vaporized mercury salts are resublimed and deposited upon the cooler parts of the apparatus. This is particularly true of the inhaling tube, which is always the coolest part of the apparatus. The consequence of this is that patients receive always an unmeasured, an accidental quantity, of these salts or vapors, and not a quantity which is measured or known. To this fact are due two accidents, namely, that one very feeble patient was violently purged, and another was salivated. However, we hope to overcome this defect of apparatus and to be able soon to give patients exact quantities of these salts. The desideratum is an inhaling tube which will bear the temperature necessary to hold the mercury salts vaporized up to the lips of the patient, and which at the same time shall be flexible. Flexibility is almost a necessity; a feeble patient cannot breathe deeply

and persistently from a stiff tube, a glass tube, such as I now use.

I have found that the only salts of mercury available for this purpose are the red oxide and calomel. All others are reduced before being volatilized. I began with the iodide of mercury. This and all others when used result in the vapor of metallic mercury only. I have found no objection, however, to the use of metallic mercury, only it is to be noted that when other salts than calomel and the red oxide are used, the patient receives the vapor of metallic mercury.

Can the vapor of mercury, or can anything inhaled, reach the bacilli in a tuberculous lung? Those bacilli which are in consolidations, provided such a consolidation is connected with a pervious bronchial tube, those in lung cavities furnished in the same manner, those in the bronchial tubes, those in the alveoli, and those in the sputum may be reached by this vapor, or by anything which may be deeply and persistently inhaled. But these bacilli are comparatively inert; they are harmless; they have already accomplished their mission of destruction, and are being extruded from the body. Those whose destruction is very much more desirable, those which have not yet, but which certainly will, produce consolidation and softening, *i. e.*, destruction of lung tissue, those in the pulmonary connective tissue, and the lymphatic sheaths of the bloodvessels, can these be reached by anything that may be inhaled? Again, if we grant that in a certain patient every bacillus has been destroyed, this is by no means synonymous with his cure. Evidences of this fact are presented daily; patients die of non-tuberculous phthisis very readily. And the tuberculous patient with every bacillus in his lungs destroyed, possesses still that fatal predisposition, and will be reinfected.

It is a question also whether mercurial vapor is a germicide. No one will deny this property to corrosive sublimate. But corrosive sublimate is not volatilizable, and volatilized mercury, volatilized calomel, and red oxide, are very different substances indeed.

Despite these theoretical objections I am encouraged to proceed with this treatment of phthisis, and when I have perfected the apparatus, and have a series of cases certainly tubercular, as demonstrated by the discovery in the sputum of the bacilli, which Dr. Matson has kindly consented to do for me, I shall report again to the Society."

Dr. R. W. Stewart exhibited his

IMPROVED URETHRAGRAPH,

and announced that it was now as nearly perfect as he could make it, and that he had made arrangements by which the profession could be supplied. As at present constructed the instrument can be introduced within the bladder, and by merely withdrawing it, it will give a tracing of the entire length of the urethra. He exhibited tracings taken from a single patient under the care of Dr. Carrington, the first before operation, and the second after operation with Holt's divulsor. The result of the operation was evident on the tracings.

Dr. J. D. Thomas complimented Dr. Stewart on the construction of the instrument, and stated that he had long since recognized the defects in Dr. Otis' urethrometer; it was too stiff; the distal side as well as the distal portion of the stricture was easily enough detected and measured, but as the "meter" was brought forward the variations in the caliber and the proximal termination of the stricture required very delicate manipulation and much experience, to gain the desired information. In this connection Dr. Thomas exhibited to the Society an improved urethrotome of his own invention. In his experience the Otis urethrotome had three defects:

1. After the blade was drawn forward and the stricture divided it was necessary to push the blade back into its sheath or recess and thus, although not intentional, make two incisions—the second one likely to be a lacerated one.

2. If more than one stricture existed the instrument had to be adjusted for each stricture, thus causing unnecessary irritation of the urethra, and

3. As the instrument opened on the principle of a parallel ruler, there was more or less displacement after the instrument was opened. Dr. Thomas demonstrated the working of his urethrotome and showed that by its use the above objections were overcome. The instrument of Dr. Thomas is made by Tiemann & Co., of New York.

Dr. Werder read a paper reporting a case of

FIBRO-CYSTIC TUMOR OF THE UTERUS.

(See page 558).

Dr. J. J. Buchanan: This operation, at which I was present, was a very difficult and interesting one. From the appearance of the patient prior to operation, I do not believe that it would have been possible for anyone to have made a diagnosis other than ovarian cystoma. The fluctuation was as distinct as though the tumor had been a single sac filled with fluid. The tumor was markedly at one side of the abdomen. It lay in front of the uterus, and in every respect that I can now think of, it exactly imitated the behavior of an ordinary ovarian cyst. With regard to the pathology, I think it rather unfortunate that there was no microscopical examination made. As to the treatment, I think it was everything that could be desired, as the result proved, although I believe that a large proportion of these cases when so treated are fatal on account of the extensive amount of tissue which has to be left to slough in the neighborhood of the peritoneal cavity. The suggestion of Dr. Werder that probably the enlargement of this growth midway between the menstrual periods was coincident with the period of ovulation, I think is hardly susceptible of proof.

Dr. Blume: Doctor Werder is to be congratulated for his successful operation. His case offers some interesting points as regards diagnosis and treatment. All authorities tell us, that an exact diagnosis in cases of large abdominal tumors often is impossible, and every one who has had an opportunity to examine such cases will confirm this. I desire to call your attention to a diagnostic symptom which has not yet been mentioned in our textbooks. Recent investigations by competent men have proven,

that in all cases of uterine tumors the endometrium is diseased. Clinical experience has taught this long ago. Hemorrhage in form of menorrhagia or metrorrhagia is known to be often a prominent symptom of fibroma and myoma. The endometritis in these cases is usually the consequence of the growth and therefore secondary. In diseases of the ovaries—oophoritis and cystic ovaries, as well as in tubal diseases, endometritis is constantly met with, and here often as a primary malady. Malignant growths of the ovaries, sarcoma and carcinoma, are also complicated with a diseased endometrium, while this complication is seldom found in cases of ovarian cystoma.

Although there are patients with large fibroma or myoma, who never lose an excessive amount of blood, and the case under discussion is an example, endometritis nevertheless always exists as a complication.

I therefore suggest, that in all cases of large abdominal tumors, after all diagnostic means to arrive at an exact diagnosis are tried in vain, the endometrium should carefully be examined. If endometritis is found to be present, the tumor may originate from the uterus. If the endometrium is found to be healthy, the tumor is proven not to be in connection with the uterus.

The treatment resorted to in this case appears to be somewhat different from the usual modus operandi. The tumor, if I understood the doctor right, was a myoma interstitialis, developing from the fundus and the right uterine wall. The ligaments were tied, the tumor cut away, and a large pedicle treated extra-peritoneally. Tumors of this kind are either enucleated and the uterine walls stitched together, or removed by supra-vaginal amputation, the pedicle treated either intra—or extra-peritoneally. The extra-peritoneal method, strongly advocated by Hegar and Kaltenbach, has given the best results. Kaltenbach lost 1 of 22 cases, equal to to 4½ per cent., Keith 2 of 38, equal to 5¼ per cent. I am in doubt, like Doctor Buchanan, whether or not it is indifferent to form a thick pedicle, as was done in this case.

A few months ago I saw a similar operation performed by Dr. Burns. The tumor, a large fibroma, broadly attached to the fundus uteri was not enucleated, but removed by a wedge-shaped incision. The remaining portion was carefully sewed, and the patient made a rapid recovery.

NEW YORK STATE MEDICAL SOCIETY.

(Concluded from page 545.)

THE second day opened as follows:

Address on Surgery (read by title), by Francis Bacon, of Connecticut.

Alcoholic Paralysis, by T. D. Crothers, of Hartford, Ct.

A Few Fads, by H. N. Didama, of Onondaga Co.

Some of the Uses of the Transfixion Ligature, by T. H. Manley, of New York Co.

The Shadow-line of Insanity, by John Shrady, of New York Co.

Then came the interesting discussion on the "Treatment of Hernia," in which the writers were Joseph D. Bryant, William T. Bull, Charles W. Brown, T. H. Squire, Wm. S. Tremaine, Roswell Park, Charles McBurney, Charles L. Squire, D. M. Totman, Frederick S. Dennis, and John A. Wyeth, all of New York State. The points of the debate related to the special mechanical treatment, the injection, open and non-open methods, the technique and the plan of procedure when gangrene of the sac or its contents becomes a complication.

"The Lantern Views" of Edward K. Dunham, of New York City, showing the details, methods and technique of microbic culture, awakened considerable enthusiasm. A collation which pleasantly accentuated the fellowship of the occasion, encroached somewhat upon the sleeping hours.

On the third and last day the "Address on Medicine," entitled the "Bacteriological Test of Drinking-Water," was delivered by Edward K. Dunham, of New York Co., and further elaborated his efforts of the previous night. The other papers were:

"The Cure of Hæmorrhoids by Excision, and Closure with the Buried Animal Suture," by Henry O. Marcy, of Massachusetts. An especially commendable one.

"Report of a Case of Ataxic Paraplegia," by Darwin Colvin, of Wayne Co.

"Observations on Dislocations of the Hip," by U. C. Lynde, of Erie Co.

The discussion on the "New Hypnotics," *e. g.*, Sulphonal, Amyl Hydrate, Hydrobromate of Hyoscine, Hypnone, Paraldehyde and Urethan then followed. The participants were William H. Flint, Austin Flint, E.G. Janeway, Charles Rice (Ph.D.), Charles G. Stockton, John G. Truax and Edward R. Squibb, all of New York State. These contributions are worthy of a very wide circulation among the profession. Then followed: "Extraction of Cataract without Iridectomy," by Charles Stedman Bull, of New York Co.; and "Two Cases of Angular Deformity of the Knee Joint," by Lewis Hall Sayre, of New York Co., in which the compensatary results of amputation with the view of wearing an artificial leg were admirably shown in the person of a patient who wore his substitute for the first time at this session.

The following nominations were announced and unanimously elected: John G. Orton, of Binghamton, President; Douglas Ayres, of Montgomery County, W. H. Burton, of Troy, E. Mott Moore, Jr., of Monroe County, William B. Eager, of Orange County, Vice-Presidents; John H. Hinton, of New York, Treasurer; E. D. Ferguson, of Troy, Secretary; John W. S. Gouley, Director of Library. First District, C. M. Klock and W. H. Biggam, of Montgomery County; Second District, Thomas Wilson, of Columbia County; Third District, H. O. Jewett, of Cortlandt County; Fourth District, Simeon T. Clark, of Niagara County; Fifth District, John J. Truax, of New York, as members of the Council. The meeting then adjourned. By way of finale, we may say that this association has a glowing future before it.

PROF. TYSON gave the introductory lecture at the University of Pennsylvania.

Book Reviews.

WOOD'S MEDICAL AND SURGICAL MONOGRAPHS. Volume III, No. 2, August, 1889. Containing: The Treatment of Syphilis at the Present Time, by DR. MAXIMILIAN VON ZEISSL; The Treatment of Inebriety in the Higher and Educated Classes, by JAMES STEWART, B. A.; and Manual of Hypodermic Medication, by DRS. BOURNEVILLE and BRICON. Price $1.00. Pp. 544. William Wood & Co., New York, 1889.

The first of the above monographs is an admirably prepared exposition of the more highly endorsed methods of treating syphilis at the present day. Though positive in his own views, and relying largely upon his own wide experience, the author has, nevertheless, carefully and impartially represented the opposing opinions upon this much-vexed question. He is a firm believer in the unicist theory of the disease, holding that the primary lesion is merely the local expression of a general infection. Hence he insists upon the uselessness of excision with or without implication of the neighboring glands. In certain cases the primary soil may be cut out, simply to remove a source of auto-infection, and so avoid unnecessary prolongation of the constitutional treatment. Likewise is he opposed to the preventive methods of treatment, either by injections into the glandular regions before their implication, or by the administration of the erroneously called antisyphilitics or antidotes to syphilis. Statistics have not established their efficacy. They simply act in this disease somewhat as they do in cadaveric or gonorrhœal poison, to place the organism in a position to wage a more successful struggle. He favors the milder methods of treatment, save in exceptional cases, and recommends the continuation of the treatment as with iodine, for at least six months or a year after the disappearance of the special symptoms. In regard to Neisser's plan of deep injections of calomel, he expresses a favorable opinion, though as yet a guarded one, in the absence of a more extensive experience with it. We commend Dr. von Zeissl's brochure to the careful consideration of those who wish to be acquainted with the views of a fearless and impartial specialist in this department of medicine.

Mr. Stewart's is a short paper, strenuously endorsing the treatment of inebriates in the homes of rural practitioners, where they may be entirely separated from relatives, sympathising friends and customary influences, and be under the constant supervision of a kind but strict supervision. Inebriety is a positive disease, and must not be confounded with mere drunkenness. Its treatment with drugs, such as capsicum, bark, etc., amounts to little more than a farce. The author recommends the complete withdrawal of the stimulus, and declares that it is perfectly safe, when the patient is constantly under the eye of a medical man. The paper is full of excellent suggestions in regard to the general management and dieting in inebriety, and, being written by one who has had a large experience in this field, will be read with special interest by the profession.

The Manual of Hypodermic Medication occupies about three-fourths of the volume. It is a translation of the second edition of this justly popular work among our foreign confrères. Among the new preparations, not to be found in the first edition, are chrysarobin, osmic acid, agaricin, antipyrine, convallaria maialis, eucalyptol, ichthyol, kairine, phenacetine and others. After a short history of hypodermic medications, and an illustrated chapter upon the methods and instruments employed, follow the descriptions and formulæ of the principal drugs administered in this way. The text has been made more available for American practitioners by the transmutation of the metric system of weights and measures into the English. Several useful tables and indexes add materially to the practical value of the work.

THE RETROSPECT OF MEDICINE. A Half-Yearly Journal, Containing a Retrospective View of every Discovery and Practical Improvement in the Medical Sciences. Edited by JAMES BRAITHWAITE, M.D. Lond. Vol. XCIX., Jan.—June, 1889. London: Simpkin, Marshall, & Co. 444 Pp.

This old friend makes its appearance this month in a new and greatly improved form. Instead of the usual paper back book, it is now presented by the publishers in the form of a compact, neatly bound volume in cloth, an improvement which at once commends itself to the reader. The long-established reputation of the "Retrospect" needs no further enhancement or recommendation by us. Each volume as it appears takes at once its place in the highest estimation of the profession, as a valuable encyclopædia of the latest advances made in the medical sciences.

Pamphlets.

Practical Notes on Urinary Analysis. By William B. Canfield, A.M., M.D., Lecturer on Normal Histology, University of Maryland. Reprint from *Maryland Medical Journal.* Baltimore, 1887.

Retained Debris as one of the Causes of Puerperal Fever. The Intrauterine Douche and Curette. By Chas. H. Earle, M.D., Chicago.

Suicide and Legislation. By Clark Bell, Esq., President of the Medico-Legal Society of New York. Reprint from the *Medico-Legal Journal*, June, 1888.

The Treatment (non-preventive) of Puerperal Fever. By Chas. H. Earle, M.D., Chicago. Reprint from the *Chicago Medical Journal and Examiner.*

The Medical Digest.

NAPHTHOL-CAMPHOR is a valuable antiseptic, whose application is not followed by pain. Salol-camphor has similar properties. They are prepared by adding 200 parts of camphor to 100 parts of betanaphthol or 300 parts of salol; reduced to a fine powder and gently warmed until they liquefy. The product is filtered and preserved in a well-closed bottle. They are miscible in fixed and volatile oils, ether, and alcohol. They have some solvent power, over iodine, cocaine and the cinchona salts. They are useful for preserving instruments, as they affect neither wood nor metal.—*Pharm. Jour.*

THE DISTRIBUTION AND DURATION OF VISCERAL NEW GROWTHS. The above was the title of the Bradshawe Lecture, delivered by Norman Moore, M.D., F.R.C.P. at the Royal College of Physicians of London, recently. After a systematic review of the evolution of our knowledge of visceral growths, from Hippocrates down to the present day, and a study of some of the well-ascertained facts in regard to their structure and natural history, the lecturer proceeded to give the results obtained from the examination of one hundred and twenty-three cases of new growths in the internal organs of the body, which had come under his observation, and included one hundred and two cases of carcinomata, and twenty-one sarcomata. As a result of this series of examinations, he arrives at the following conclusions:

1. That the *œsophagus* is a common seat of new growth in men, a very rare one in women.

2. That, in carcinoma of the œsophagus, the new growth is rarely confined to that organ.

3. That it may grow, along with the œsophagus, into the stomach.

4. That it may grow directly into the lung, and that this is a frequent occurrence.

5. That it may grow directly into the mediastinal glands.

6. That it may, though rarely, infiltrate the dorsal vertebræ.

7. That it is frequently associated with widespread secondary growths, of which the commonest seat is the liver, and that, after the liver, the lungs, heart, and kidneys are more often affected than any other viscera.

8. That the *stomach* is a common seat of new growth in both sexes.

9. That carcimona of the stomach generally grows from the pylorus towards the cardiac end of the cavity.

10. That the growth is rarely continued into the œsophagus, but more often than into the duodenum.

11. That, in about one-fourth of the cases, the growth extends directly into the lymphatics, along one or both curvatures of the stomach, forming dense masses, which may often be felt through the abdominal wall.

12. That, after these lymphatics, its most frequent seat of growth in continuity is the liver.

13. That it may also grow in continuity, though with less frequency than into the liver, into the diaphragm, omentum and mesentery, pancreas and transverse colon, and less often still into the ascending colon, spleen, vertebral column, and vena cava inferior.

14. That in two-thirds of the cases there are secondary growths, and that in one-third these are widespread, affecting one or more regions.

15. That the commonest seat of secondary growth is the liver, and next to it remote lymphatics, especially the glands in the hilum of the liver, the lumbar and mesenteric glands, and those of the mediastinum.

16. That after these the pancreas and lungs are most often the seat of secondary growth, and with nearly equal frequency.

17. That secondary growths are rare, but may also occur (in the order of frequency) in the peritoneum generally, and in the kidney, and least often and with equal rarity, in the heart, spleen, and supra-renal bodies.

18. That carcinoma of the *colon* tends to spread, by direct continuity, and may thus, according to its situation, penetrate the stomach, duodenum, ilium, or abdominal wall.

19. That it rarely has secondary growths, and that when these occur they are commonest in neighboring lymphatics, and may rarely be found in the liver.

20. That, in carcinoma of the *rectum*, a majority of the cases have neither growth in continuity nor secondary growths.

21. That the lumbar glands and the liver are the most frequent regions of secondary growth when occurring.

22. That the pancreas is sometimes infiltrated.

23. That the stomach is a more frequent seat of new growth than the œsophagus, and the œsophagus than the colon, and that, notwithstanding its greater length and therefore greater area of epithelium, the small intestine is the least frequent of all.

24. That new growths of the œsophagus lead to most widespread secondary growths, and new growths of the colon to the least widespread.

25. That new growths of the colon have the greatest tendency, perhaps owing to their situation, to grow directly into the other parts of the alimentary canal.

26. That carcinoma of the *gall bladder*, and *large bile duct* (generally the common duct) usually grows directly into the liver.

27. That secondary deposits, if present, are not widespread.

28. That their most frequent seat is the abdominal lymphatics, but that they may occur, in order of frequency, in the lungs, the liver, and the peritoneum.

29. That the *liver* is a rare seat of primary new growth.

30. That primary new growth in the *pancreas* occurs in both sexes.

31. That, in carcinoma of the pancreas, growth in continuity is rare, but may take place into the stomach, gall-bladder, transverse colon, or duodenum.

32. That secondary growths are not usually widespread, and that their commonest seat is the liver.

33. That they may also occur in the lungs, kidney, peritoneum, and heart.

34. That primary new growth in the *lungs* may be a carcinoma or a sarcoma.

35. That endothelioma of the *pericardium* may grow directly into the lung.

36. That its secondary deposits are usually widespread, and may include the liver, pancreas, spleen, kidney, and supra-renal body.—*Medical Press and Circular*, September 4.

GLYCERIN reduces the causticity of carbolic acid, provided no water is present. In cases of burns by this acid the skin should be washed with alcohol or pure water-free glycerin.

In a paper published in the *Bul. Gen. de Ther.* upon secondary post-partum hemorrhage M. Misrachi arrives at the following conclusions :

1. Secondary post-partum hemorrhage is an accident always alarming, often dangerous, and important to be stopped with the least possible delay.

2. Intra-uterine injections, which are an enormous improvement over former methods of treatment, are not always efficacious, and often require considerable time before effecting a cure.

3. The antiseptic dressing of the uterus by means of a species of curette or some other convenient instrument, is a method of treatment as inoffensive and much more rapid and effectual than intra-uterine injections.

Treatment of Diphtheria.—M. Gaucher employs the following formula :

℞.—Camphor . . . . . 20 grammes.
Castor oil . . . . . 15 grammes.
Alcohol at 90° . . . . . 10 grammes.
Phenic acid (crys.) . . . . . 5 grammes.
Tartaric acid . . . . . 1 gramme.
M.—Sig. Apply locally.

—*La Tribune Médicale.*

Iodoform in Cystitis.—

℞.—Iodoform . . . . . 50 gr.
Glycerine . . . . . 40 gr.
Distilled water . . . . . 10 gr.
Tragacanth . . . . . 25 gr.
M.—D. S. Add a spoonful of this emulsion to one-half liter of warm water and shake thoroughly.

The injections should be repeated every three days until four have been given, when once a week will suffice.—*L. Frey, Revue de Ther.*

An Abortive Treatment of Carbuncle by Iodoform.—This treatment consists in :

1. Disinfecting the diseased part with a carbolic solution of 1 part to 40, or with a solution of 1 part in 2000 of sublimate.

2. Spreading upon the surface a layer of powder prepared as follows :

℞.—Fine powdered Iodoform,
Oxide of Zinc . . . . . equal parts.
M.—S. A.

This dressing should be made with a brush dipped in phenic oil, and repeated twice daily and continued until the complete drying up of the tumor.

In a report read by M. René Lavalle at the Academy of Political and Moral Sciences, was the following :

At Reichemberg in Bohemia 6 per cent. only of the recruits were found good for the service, and of 365 weavers, not more than 9 per cent. At Berlin in 1000 recruits scarcely 40 were fit for service. War and manufacturing work—these are the two factors in the degeneration of the race ; war because it destroys the strongest and best constituted men ; industry because it atrophies them. The people to whom the future belongs are the agriculturalists.—*Revue de Ther.*

The Treatment of Placenta Prævia.—In a paper read before the Obstetric Section of the British Medical Association at Leeds, in August, Dr. J. Braxton Hicks advances the following rules which should be observed by obstetricians when dealing with that dangerous complication of pregnancy, placenta prævia :

1. After diagnosis of placenta prævia is made, proceed as early as possible to terminate pregnancy.

2. When once we have commenced to act, we are to remain by our patient.

3. If the os be fully expanded and the placenta marginal, we rupture the membranes and wait to see if the head is soon pushed by the pains into the os.

4. If there be any slowness or hesitation in this respect, then employ forceps or version.

5. If the os be small and placenta more or less over it, the placenta is to be carefully detached from round the os; if no further bleeding occur we may elect to wait an hour or two, but should the os not expand, and if dilating bags are at hand, the os may be dilated. If it appears the forceps can be admitted easily, they may be used, but if not, version by combined external and internal method should be employed, and the os plugged by the leg or breech of the fœtus ; after this is done, the case may be left to nature, with gentle assistance, as in footling and breech cases.

6. If the os be small, and if we have neither forceps nor dilating bags, then combined version should be resorted to, leaving the rest to nature, gently assisted.

7. If during any of the above manœuvres sharp bleeding should come, it is best to turn by combined method in order to plug by breech.

8. Where the death of the fœtus occurs before the end of the seventh month, version by combined method, no force following, is the best plan.

The after treatment must be conducted on the modern principles. Should oozing occur after the expulsion of the placenta, the swabbing of the lower uterus by styptics will be easy, and inasmuch as the outlet of the uterus is liable more especially to be blocked by adherent clots, it will be wise to irrigate the uterus daily with some antiseptic solution, or insert iodoform pessaries in the vagina, particularly if the irrigation cannot be done.

—*Medical Press and Circular.*

For Acne.—Gailleton has employed with success the following pomade :

℞.—Iodochloride of mercury . . . . . gr. ivss.
Ung. simp . . . . . ℥j
M.—S. Apply with prolonged frictions. The reaction is very energetic.

—*Revue de Ther.*

For Infantile Eczema.—

℞.—Acid boric . . . . . gr. lxxxj.
Vaselini . . . . . ℥j.
Bals. Peruan . . . . . gr. vijss.
M.—S. Apply to the parts affected.

—*Delapert, Revue de Ther.*

HINTS IN URINARY DISEASE. — Ultzman's work on "Urinary Disease" contains a number of excellent suggestions which, without being novel, present the treatment of some more common forms in a concise modern light. *Urethritis anterior gonorrhoica* is due to invasion of Neisser's gonococci and has a typical course, beginning at the external orifice, and gradually invading backward, until, in the fourth week, the bulbous urethra is attacked, and thus, in some cases, the case terminates. The treatment required is really, besides careful diet and rest, only cleansing of the canal with a gently astringent injection of alum, zinc or potass permanganate. The object is to render the cyclical course of disease free from complication. Meat should be avoided, except white meat; stimulants, coffee and spices, to be avoided. A suspensory bandage should be used. In active inflammation, cold compresses and injections of three per cent. boric acid solution; later a solution of alum, sulph. zinc and carbolic acid, about one grain each to the ounce, urinating three to six times daily. This solution is to be increased in strength as the tenderness ceases. Chronic gonorrhœa Ultzman treats by sounds, splitting of external meatus if necessary, by deep irrigation through a catheter, or by bougies of tannin and zinc with cocoa butter.

For treatment of strictures Ultzman advises either temporary or permanent dilatation, with the following rules:

1. Only new, perfectly disinfected sounds or bougies should be used.

2. Always begin with a number which on the previous day passed easily, then use the larger ones.

3. When a catheter can be introduced, it is useful to irrigate the canal for disinfection after each dilatation.

4. If bleeding occurs, all attempts should cease, order patient to be quiet, refrain from urinating several hours, and apply cold compresses to the perineum.

5. No sound should be introduced without previous examination of the fresh urine. If albumen is found present or increased, it is safer to defer treatment.

In very narrow strictures, Dunreicher's method is to be commended, viz.: to introduce a number of filiform bougies in succession, retaining all until one passes.

Elastic bougies should lie ten minutes; From No. 1., English, a stricture should be dilated to fifteen with bougies; then sounds up to twenty-four should be used. Now patient may introduce lead-rubber bougies, before retiring to bed, allowing them to remain one-quarter to one-half hour, first daily, later twice a week. *Permanent*, slow dilation is executed by allowing the instrument to remain twelve hours, the urine being evacuated alongside the bougie. Each day two numbers may be advanced, taking care to retain a size which passes easily. In this manner Ultzman claims to dilate strictures in four to five days without danger.

In retention due to stricture he recommends warm applications, baths and narcotics, followed by injections of a few drachms of oil, which is gently forced back by stroking. The penis is now firmly drawn forward, and a filiform bougie is introduced and retained ten minutes. The patient now rises and is ordered to pass urine, while the bougie is being withdrawn slowly. This process is repeated several times until the bladder is emptied. He regards this method as "excellent and always to be applied."

Ultzman regards internal urethrotomy as not to be prefered to dilatation in results. External urethrotomy cannot be dispensed with in some cases.

VAGINAL MYOMECTOMY.

Vaginal enucleation of uterine fibroids has gone out of vogue, since laparotomy has become so fashionable. Chrobak (*Med. Jahrbuecher*, ix, 535) regards enucleation as more in accordance with modern conservative surgery than laparotomy.

As a first condition all operators demand a short, wide, soft cervix; a narrow, long rigid one is a contraindicator. This may be correct when very large tumors are involved. But he advises enucleation in ordinary sized tumors, whenever it seems feasible to deliver them without great force. For this purpose a capacity for dilatation of the cervix suffices, and in one case (13) an absolutely virgin uterus did not prevent the enucleation of an egg-shaped growth 6 by 4.5 cm. diameter. He begins dilatation by tupelo tents; when the cervix is almost dilated, he increases the opening by making with scissors five or six radiating incisions, which are stitched after the operation. The best time for operation is immediately after the menstrual period. Submucous fibroids are the most suitable, but he has enucleated two multiple subserous tumors. Instruments should be avoided as the fingers must do most of the work.

A speculum is rarely used; the cervix is grasped high up by hooks, and the uterus drawn down. The incision is best made across the point where the tumor clearly leaves the uterine wall; in high tumors the most accessible point is chosen. The splitting is done by a probe-pointed knife or with a curve polypus scissors; the incision being widened by the finger or dull raspatory. The cautery iron is dangerous.

Enucleation should be made with the fingers, which may be aided by twisting with hooks, rarely by cutting.

Chrobak deprecates the use of violence, although a certain amount is needed. Instruments for grasping the tumor securely are, however, required. Very large tumors may be compressed by the cephalotribe or cranioclast, or they may be removed piecemeal, after applying elastic ligature. Patients' nates, vulva and vagina are rendered aseptic by irrigation and brushing with sublimate solutions, an iodoform pencil is put into the uterus, iodoform gauze tampon into the vagina, which is removed just before operation. During the latter a weak salicylic stream is played upon the parts; the hands are dipped in cold sublimate solution when they become numb. After enucleation the uterine cavity is thoroughly irrigated and swept with cotton tampons dipped into sublimate or carbolic solution. Loose remnants are not removed; they shrivel. Chrobak tampons the uterus and drains it with iodoform wicks, and gives ergotin

subcutaneously. On the fourth or fifth day the dressings are removed, unless earlier demanded by a rise of temperature. Chrobak publishes nine cases in addition to his previous eleven cases, of which one died. His communication certainly deserves attention in this day of indiscriminate laparotomies.

For Phthisis.—

℞.—Hydrarg. biniodid . . . . . gr.xv.
Potass. iodid . . . . . gr.xv.
Aquæ dest . . . . . oij.
M.—S. For use with the atomizer.

—Rueff, Revue de Ther.

Incompatibility of Antipyrine with other Drugs.—M. Charles has called attention to the precipitate which is formed by mixing solutions of antipyrine and cinchona, and M. Ferand has made later some experiments which warrant him in saying, that in mixtures containing antipyrine and cinchona all the active principles of the potion are precipitated and leave in the filtered liquid scarcely a perceptible trace of antipyrine and the alkaloids. He notices, as did M. Charles, that the precipitate is readily soluble in weak acids, from which he concludes that the potion does not become inert, as the precipitate should dissolve in the gastric juice.

Treatment of Diphtheritic Conjunctivitis.—M. Agnifor Blanch considers this disease first as a local and then a general disease, and favors the increase of the conjunctival secretion as a means of detaching and eliminating the false membrane. This treatment consists of lavings of boric acid or of sublimate 2 to 1000 solution, the detachment of the false membrane with a forceps, the cleaning of the mucus with a linen cloth dipped in lemon juice or tartaric acid, and then the application upon the conjunctiva of a substance intended to prevent the false membrane from being reproduced. This substance is Helentine, which appears to act specially upon the microbes of diphtheria, and which besides increases the vascularity of the conjunctiva and its secretion. Then it is necessary to avoid absolutely from moist heat.

—La France Médicale.

M. Blainville, pharmacist, records a new incompatible with antipyrine; having had occasion to mix 4 grammes of antipyrine and 5 grammes of hydrate of chloral, and 15 grammes of water, he found the mixture became milky, then clearing deposited an oleaginous liquid. Decanted, this liquid possessed neither the taste of antipyrine nor of chloral, but resembled coriander seeds.

Upon the subject of incompatibles, which are discovered each day by pharmacists, M. Ferand remarks, that they should avoid mixing substances as complex as antipyrine with chemicals capable of modifying its composition, and consequently its physiological action.

Formulas the most simple, said he, such as distilled water sweetened, should be the rule when prescribing a new body used in therapeutics before all its chemical characteristics are thoroughly studied.

—La France Médicale.

Medical News and Miscellany.

Dr. F. D. Castle has removed to 1502 Walnut Street.

Dr. Andrew Graydon has removed to 1338 Walnut street.

Professor Keen was too ill to give his introductory lecture.

There were twenty-one deaths from starvation in London last year.

Foot-ball playing has commenced at the University of Pennsylvania.

It has been stated that next year the University is to have a new Provost.

The outbreak of cholera in Mesopotamia is exciting apprehension in Russia.

Artificial cloves have appeared in the market. Theatre-goers, take warning!

In La Grasse, France, where perfumes are largely made, phthisis is said to be unknown. (?)

Citron cream is a good application for cracked lips. Ung. hydrarg. ox. rub. is another.

English medical journals herald the opening of the foot-ball season with the record of a death.

By slowly sipping cold water it is said that many cases of headache may be cured,—Psychotherapy?

The authorities of Queen's College, Belfast, have decided to admit female students of medicine during the ensuing session.

George P. Thomas has been elected Resident Physician of the Jewish Hospital, in place of A. W. Rocap, resigned.—*Record.*

A case of smallpox has appeared in Chicago, in the person of a young man who had just come from Havre, where the disease now prevails.

In the report of the proceedings of the *Mississippi Valley Medical Association*, Dr. Francis Dowling's name was erroneously spelled with a B.

Elementary instruction in medicine shall hereafter be given in the Orthodox seminaries of the Russian Empire, by decree of the Holy Synod.

Eighteen premature infants have been saved by the couveuses at the Philadelphia Woman's Hospital. No cases of failure have as yet been recorded.

We regret to hear of the death of the senior partner of the firm of Lutz & Movius, of New York. Mr. Lutz was one of those gentlemen with whom a business interview was a pleasure.

Sir Edwin Arnold says that in India, with 200,000,000 inhabitants, a love-match never occurs; and yet there are more happy marriages, happy homes, and pure domestic relations than anywhere else in the world.

We judge that Mr. Arnold must be about 80 years old.

In our recent report of the proceedings of the *Mississippi Valley Medical Association*, the name of the treasurer should have been Dr. C. F. McGahan, of Chattanooga, Tenn., instead of Dr. Chapman, who was former treasurer.

The following are the selections for this season's Health Talks to Young Men in the Hall of the Young Men's Christian Association, upon the evenings of the dates assigned. Music or gymnastics will precede the lectures: Dr. Frank Woodbury, Digestion and Diet, October 8. Dr. J. P. Crozier Griffith, Respiration and Circulation, October 17. Dr. Charles K. Mills, The Brain and Its Functions, October 24. Dr. De Forest Willard, Some Emergencies and How to Meet them, October 31.

The recent session of the International Congress of Medical Jurisprudence was successful beyond the most sanguine expectations of its promoters. It perfected a permanent organization and provided for the selection of an additional vice-president from each State and Territory of the American Union, and from each foreign province, State and country who had members in the organization that took an interest in the success of the movement.

The expenses of publishing all the papers read at this Congress, with a record of its transactions and the proceedings at the banquet, will fill a large volume, the expense of which is estimated will be about $700. The Executive Officers were authorized to elect additional members into the organization, the only expense of which is the enrolling fee of $3.00, which entitles the member to the *Bulletin* free.

Co-operation is earnestly solicited in all localities, and names will be laid before the Executive Officers for enrollment as members on receipt of the enrolling fee, which can be sent to any officer of the body.

The officers elected by the Congress, held June 4th to 7th, 1889, in New York, were as follows: President, Clark Bell, Esq., of New York; Secretary, Moritz Ellinger, Esq., of New York.

To Contributors and Correspondents.

All articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, United States Army, from September 29, 1889, to October 5, 1889.

Kendall, William P., Assistant-Surgeon. Granted leave of absence for one mouth. S. O. 93, Dept. of the Platte, October 2, 1889.

Tremaine, William S., Surgeon. Relieved from temporary duty at Fort Leavenworth, Kansas, and will return to his home, Buffalo, N. Y. Par. 13, S. O. No. 230, A. G. O., October 3, 1889.

Billings, John S., Surgeon. Detailed as delegate to represent the Medical Department of the Army at the annual meeting of the American Public Health Association, to be held at Brooklyn, N. Y., October 22, 1889. Par. 10, S. O. No. 230, A. G. O., October 3, 1889.

Poindexter, Jefferson D., Assistant-Surgeon. Granted leave of absence for one month. S. O. No. 113, Headqrs. Dept. of Dakota, September 30, 1889.

Pope, Benjamin F., Surgeon. Relieved from duty at Fort Clark, Texas, and will report for duty to commanding officer, Whipple Barracks, Arizona Territory. Par. 11, S. O. No. 230, A. G. O., October 3, 1889.

Adair. George W., Captain and Assistant-Surgeon. Leave of absence for one month. S. O. 90, Headqrs. Dept. of the Platte, September 25, 1889.

Pope, Benjamin F., Major and Surgeon. By direction of the Secretary of War, the leave of absence granted in S. O. No. 54, August 17, 1889, Dept. of Texas, is extended one month. Par. 6, S. O. 224, A. G. O., September 26, 1889.

Chapin, Alonzo R., Captain and Assistant-Surgeon. With the approval of the Secretary of War, leave of absence for fourteen days is granted. Par. 10, S. O. 223, A. G. O., September 25, 1889.

Burton, Henry G., Captain and Assistant-Surgeon. By direction of the Secretary of War, will report in person, on the expiration of his present sick-leave of absence, to the commanding officer, David's Island, New York, for temporary duty at that station, and by letter to the superintendent, recruiting service. Par. 3, S. O. 223, A. G. O., Washington, September 25, 1889.

Loring, Leonard Y., Major and Surgeon. Station is changed by direction of the Secretary of War, from Fort Mojave, Ariz. Ty., to Fort Wingate, N. Mex., and he will report for duty at the latter accordingly. Par. 7, S. O. 219. A. G. O., September 20, 1889.

Changes in the Medical Corps of the United States Navy for the week ending October 5, 1889.

Harmon, George E. H., Surgeon. Detached from the U. S. S. Constellation, and ordered to Naval Academy.

Lownes, C. H. T., Assistant-Surgeon. Detached from the U. S. S. Constellation, and to Naval Academy.

Winslow, George F., Surgeon. Ordered to Marine Rendezvous, Boston.

Henry, Charles P., Assistant-Surgeon. Ordered before the Retiring Board for examination.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service for the six weeks ended October 5, 1889.

Fessenden, C. S. D., Surgeon. Granted leave of absence for thirty days. October 3, 1889.

Wyman, Walter, Surgeon. Granted leave of absence for thirty days. September 3 and 21, 1889.

Sawtelle, H. W., Surgeon. Granted leave of absence for seven days. September 26, 1889.

Austin, H. W., Surgeon. Granted leave of absence for thirty days. September 9 1889.

Gassaway, J. M., Surgeon. When relieved at New Orleans, La., to rejoin station at Cairo, Ill. September 30, 1889.

Goldsborough, C. B., Surgeon. Leave of absence extended thirty days, on surgeon's certificate of disability. September 16, 1889.

Armstrong. S. T., Passed Assistant-Surgeon. Relieved from duty at New York; ordered to command of service at Cleveland, Ohio. September 17, 1889.

Ames, R. P. M., Passed Assistant-Surgeon. Assigned to duty at New Orleans, La., upon expiration of leave of absence. September 30, 1889.

White, J. H., Passed Assistant-Surgeon. Leave of absence extended thirty days, on surgeon's certificate of disability. September 21, 1889.

Norman, Fenton, Assistant-Surgeon. Granted leave of absence for thirty days, to take effect when relieved. October 4, 1889.

Pettus, W. J., Assistant-Surgeon. Ordered to Portland, Me., for temporary duty. September 26, 1889. Granted leave of absence for twenty-six days, to take effect when relieved. October 6, 1889.

Kenyoun, J. J., Assistant-Surgeon. Granted leave of absence for thirty days. September 28, 1889.

Medical Index.

We purpose on this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Accoucheur, the, and his forceps, Barnes. The Practitioner and News, Sept. 28, 1889.

Acute intestinal obstruction complicating strangulated hernia; herniotomy, with subsequent laparotomy recovery, Way. Med. News, Oct. 5, 1889.

Adénites aigues, par le Dr. Daudois. Revue Medicale de Louvain, Juillet, 1889.

A few clinical cases, showing the value of oxygen combined with nitrogen-monoxide, in the treatment of pulmonary and other troubles. E. C. Titus, M.D. N.Y. New York Medical Record, Oct. 5, 1889.

Aseptic surgery, Burrell. The Boston Med. and Surg. Journal, Oct. 3, 1889.

Angular curvature, nature of the physiological failures which superinduce vertebral deformity, Taylor. New York Med. Journal, Oct. 5, 1889.

Antipyretics in various diseases, attended with abnormal elevation of animal heat; general propositions with reference to the employment of, Jones. Virginia Medical Monthly, Oct., 1889.

Antiseptic treatment and protection for the membrana tympani in perforations, the result of otorrhœa, the value of, Turnbull. Virginia Med. Monthly, Oct. 1889.

Cæsarean section, a case of, Hays. N. C. Med. Jour., Sept., 1889.

Calcul vesical. Taille hypogastrique; par le Dr. Thisguen. Revue Medicale de Louvain, France, Juillet, 1889.

Chlorosis, simple anæmia, and pernicious anæmia, including leucocythæmia and Hodgkin's disease, Henry. Medical News, Oct. 5, 1889.

Chronic diseases of the upper air-passages, on the connection of, Freudenthal. The Journal of the Amer. Med. Ass'n. Oct. 5, 1889.

Cocaine, as a local anæsthetic, Long. The Peoria Medical Monthly, Sept., 1889.

Colon, flushing of the, Etheridge. The Peoria Medical Monthly. Sept., 1889.

Creasote, in fifty cases of disease of the air-passages, the value of, Watson. Virginia Med. Monthly, Oct., 1889.

Deafness, its causes and prevention, from a rational standpoint, Hays. N. C. Med. Journal, Sep., 1889.

HÆMATOMA OF THE VULVA IN THE NON-PUERPERAL STATE.

WITH A REPORT OF THREE CASES.

BY KINGMAN B. PAGE, M.D.,
NEW YORK CITY.

Hæmatoma of the vulva, "a tumor formed by a mass of clotted blood effused into the tissue of one labium or the areolar tissue immediately surrounding the wall of the vagina."
—T. GAILLARD THOMAS.

ALL our standard text-books on midwifery mention this injury as one of the complications of labor, but the literature of the subject of its occurrence in the non-puerperal state is but scant indeed, and by many gynæcological writers of systematic treatises is totally ignored.

Authors differ widely as to the frequency of its occurrence. Thomas[1] states that, "in an experience of thirty years I have met with but three cases;" while Velpeau claims it to be as frequent in the non-puerperal as in the puerperal state. Grailey Hewitt[2] writes: "This is not by any means a common affection," and regards it in its relations to the puerpera. By West and Duncan[3] it is ignored. Nonat et Linas[4] mention it, without giving cases, as the result of blows, falls, or as an accident of awkward coitus. Barnes[1] refers to it only in its obstetrical light. Schroeder[2] briefly mentions the case of Von Franque's and dismisses the subject. Winckel[3] writes: "Altogether, I have seen five cases in the non-gravid state."

We have here the testimony of gynæcologists of great experience, several of them being residents of the great cosmopolitan cities of New York, Paris, London and Berlin, as to the rarity of the injury; while Velpeau stands alone in his opinion.

An anatomical study of the vulva discovers a large vascular plexus situated comparatively superficially, surrounded by tissues which are also exceedingly vascular.

A slight injury to these parts readily causes an extravasation of blood, and severe violence, rupturing some of the larger veins or even the bulbs themselves, causes an extravasation of blood in such quantities as to seriously collapse the patient. By its anatomy we can clearly see that in a rupture involving the larger veins and the bulbs, there is nothing but the highly elastic and distensible tissues of the labia majora to form the sac and exert a restraining influence. This explains the extraordinary size and capacity of the hæmatoma in one of the cases I shall report.

The question will now arise, How is it that, with tissues so favorably constituted for the formation of blood extravasations, they so rarely occur?

[1] "Diseases of Women." Amer. Ed.
[2] "Diseases of Female Sexual Organs." Vol. X, Ziemssen's Cyclopædia.
[3] "Diseases of Women." Parvin's Ed.

The true explanation, I believe, will be found in the following lines, quoted from Dr. Ranney's monograph:[1] "In the nude, erect female, only the mons veneris is seen; the external genitals being hidden by the thighs."

So that the violence of falls, blows, etc., is usually received on the mons veneris or thighs, the vulva escaping, except in those cases where the woman, taken by surprise, or as the result of careful and purposely delivered blows, receives them directly on the external genitals.

The nature of the injuries which have caused a vulvar hæmatoma are as many and varied as those which cause any other surgical lesion. Nonat et Linas cite awkward coition; Von Franque, straining at stool; Gempe, in a nurse, twenty years of age, who had lifted patients a good deal; Winckel, the result of a fall against the side of a bath-tub. In my cases, one was caused by a fall astride of the rung of a ladder, the second by a well-applied kick, the third the result of a fall against the corner of an ice-box.

The symptoms are the formation of a tense, elastic, non-fluctuating tumor in the labium, following local injury, accompanied by more or less collapse and pain.

The treatment: cold applications, pressure, or incision and drainage.

I have been extremely fortunate in my experience with this injury, having had under my charge three cases in the past two years, two of which are of more than ordinary interest.

HÆMATOMA—RIGHT LABIUM MAJUS.

CASE I.—Miss R. M., aged nineteen years, on December 18, 1887, while hanging a picture, slipped and fell astride the rung of a step-ladder. She managed to get up from this awkward position unaided, but was immediately seized with an attack of vomiting and faintness, with severe pain in the region of the groin.

I saw her about two hours after the accident, and on examination found that a tumor about the size of a hen's egg had formed in the right labium majus. Ice was at once applied, and cold applications kept up for several days; the pain at no time was very severe. Under this treatment the swelling diminished somewhat; the cold applications were discontinued, and mild counter-irritation used for a period of ten days, after which time all treatment was discontinued, and at the expiration of a month the patient reported the swelling to have totally disappeared.

HÆMATOMA COMPLICATED BY CHANCROIDAL INOCULATION.

CASE II.—Miss May H., aged twenty-six years (an obstetrical virgin), on the night of 6th of November, 1888, received from her "friend," as a slight punishment for inoculating him with a chancroid, a well-applied kick on the vulva. The woman went into a state of depression almost amounting to collapse, on which her gallant "friend" immediately deserted her. She was found in this condition some hours afterward by the other inmates of the house, by whom she was dosed liberally with brandy without her true condition being understood.

A physician resident in the locality was called in, and seeing the serious condition of the patient, recommended her removal to the hospital, refusing to take charge of the case. Late in the afternoon of the next day I was requested to see the case. The patient was a finely-developed blonde, syphilitic. By this time she had recovered somewhat from the shock, but was too much "exhilarated" to give any sensible account of herself, or to admit of any extended local treatment. Ordered ice-bags to the vulva, and abstention from liquor. November 8 the patient had somewhat recovered from her debauch. Complained of severe pain and throbbing in genitals. The woman was placed on a table; a thorough examination revealed a shocking condition. The whole vulva was greatly swollen, especially the left labium majus which was swollen to the size of an orange. The nymphæ were torn, the frenum torn from the clitoris, and the clitoris itself lacerated. There had been quite a profuse hæmorrhage from these lacerations. The edges of several of the larger tears were trimmed off and united; the whole vulva freely irrigated with corrosive sublimate solution, 1–2000, then covered with iodoform gauze, and the ice-bag reapplied. She then passed out of my hands until December 1, when I was again requested to take the case. As to what had been done in the meantime I have little knowledge, as Miss H. was very non-communicative, save that she had gone to the country, and the "thing had burst." Professional interest was the only inducement which I had to take the case, and it rewarded me.

Examination revealed, if possible, a worse condition than before. The hæmatoma had discharged, as the patient stated, and had undoubtedly become infected (from the chancroid, which she admitted having at the time of the injury). In place of the tumor was found a large cavity, whose walls were sloughing, and formed on one side by the vagina, superiorly by the abdominal skin, externally and inferiorly by the skin and subcutaneous tissue of the thigh. The inguinal and femoral glands had suppurated, the labium of this side was totally destroyed, the right side was comparatively in good condition.

Nitric acid was, as freely as compatible with safety, applied to the sloughing tissue, constant irrigation with corrosive sublimate solution 1–3000, used for nearly a week, at the end of which time the wound looked somewhat cleaner and better. Strong nitrate of silver solution was then applied to greater parts of the sides of the wound, and iodoform dusted on. This treatment was continued for two weeks, at the end of which time the wound looked nearly healthy. Simple iodoform dressings were used with balsam of Peru, until the whole surface of the ulcer, save a part about two inches square, had healed. This surface obstinately refused to heal; resort was then had to skin grafting, and finally, by this means, the ulcer was healed; at the expiration of five months from the receipt of original injury, as a result of which the

[1] "Topographical Relations of the Female Sexual Organs." A. L. Ranney, M. D. William Wood & Co., N. Y., 1883.

patient was left minus the left labium majus and minor, and the vagina much distorted and drawn to the left.

CASE III.—Mrs. Marie R., forty-four years of age, M. VI para. Mrs. R. had been hanging her wash from the fire escape, and in re-entering the room by the window fell, with her legs wide apart, on the corner of the ice-box. She fainted, and on gaining consciousness, had a severe vomiting attack, and suffered greatly from shock. Her family much frightened by the syncope, called in the nearest physician, who happened to be an irregular. He directed cold applications, and gave a narcotic for the painful tense swelling he found in the right labium. The case remained in his charge for ten days; the tumor gradually increasing in size and becoming more painful, the patient, in the meantime, passing but little urine —twenty ounces per diem. During this time he alternated hot and cold applications.

On June 3, the tenth day of the injury, the swelling rapidly increased in size, and the pain became intense, on which he resigned the case, stating that it necessitated the services of a surgeon.

On June 4, 3 A. M., the pain during the night had been so intense that on recommendation of a relative on whom I had recently operated, I was requested to see the case. A hurried examination showed the necessity of operative procedure, as the tumor wat the size of a large cocoanut and tense as a drumhead. I gave the patient a hypodermic of morphine to relieve the pains; by catheter obtained urine for examination, tumor interfering with micturition. Urine examined—sp. gr. 1026, no albumen, no sugar, large quantity mixed urates, reaction neutral, color deep yellowish red.

Operation at 2:30 P. M., was in presence of Dr. J. H. Forman, and one of my students, Mr. Chas. S. Woodward. When the patient was placed on the table we were all surprised at the great extent of the ecchymosis. The whole abdomen from the sternum to the pubis, round to the spine and down thigh to knee on the right side, was mottled by blue, dark green and yellowish coloration, producing a most striking appearance. The tumor, as large as a cocoanut, prevented the thighs from being brought into apposition; but it was only on separating them that the size of the hæmatoma was realized. Extending from the mons veneris to the anus, and overlapping the whole left side of the vulva was a tense, elastic, non-fluctuating, exquisitely tender swelling, involving the right labium majus, and presenting the same mottled coloration so striking on the abdomen. Ether was administered by Dr. Forman. The mons and labium were shaved, scrubbed with soap and water, washed with bichloride 1–1000, and then with iodoform ether. An incision two inches in length was made on the under side of the tumor, and twenty ounces of black clotted blood evacuated, the cavity scraped out with a Thomas blunt curette. The extent of the cavity and its boundaries was then ascertained. The bulb of the vagina had been ruptured, and the extravasated blood was effused under the subcutaneous tissue of the mons, down the internal surface of the thigh and backward to the anus. The whole hand could be introduced without difficulty. The cavity was thoroughly irrigated with bichloride 1–2000. A drainage tube was introduced, and an iodoform dressing applied, which was covered with rubber tissue, retained in place by a T bandage, vagina irrigated and tamponed to cause pressure on dressing in wound. Saw Mrs. R. again the same evening. She had recovered from the ether, but had only passed two ounces of urine; ordered to drink a glass of water hourly.

June 5. Complains of pain during the night, which passed off toward morning; passed but little urine, no albumen; has a sense of constriction in chest; examined dressing; no hemorrhage.

June 6. No pain. Moved bowels with citrate of magnesia. Quantity of urine passed in twenty-four hours about four ounces; no albumen. Has slight ether bronchitis. Pulse poor. Complains of weakness. Continued drinking cold water. No headache.

June 7. Examined wound. No hæmorrhage or suppuration. Withdrew drainage tube. Slight swelling over mons. Urine increasing in amount. No pain. Bowels moved. Bronchitis improving.

June 9. Wound healing by first intention. Swelling over mons the same. Slight induration in the perineum. Urine nearly normal in amount.

June 12. Patient sat up for a time. Wound nearly healed.

June 16. Urine normal in quantity. Bronchitis ceased. Labium still a little enlarged. Feels perfectly well.

June 20. Discharged. The vivid mottling of the abdomen still present. Patient informs me that it lasted for a period of nearly two months.

I have detailed this and the preceding case at some length for the purpose of comparison. They are worthy of it. The second case shows the result of neglect and the mutilation resulting from it, while the last case shows the results to be obtained by thorough and careful antisepsis.

My cases have been numerically too few in number to afford substantial ground for deductions as to treatment, but in any case when, after a full trial of the controlling influences of cold applications, we meet with failure, the tumor either increasing in size or not showing signs of re-absorption, as in case 3, when the tension is so great as to threaten spontaneous rupture, I believe that it is our duty to open the sac, and thus rapidly end the danger.

312 EAST 116TH STREET.

THE MODE OF ENTRANCE OF THE BACILLUS TUBERCULOSIS INTO THE SYSTEM.

BY LAWRENCE F. FLICK, M.D.

ONE of the most important questions to be settled about the etiology of tuberculosis, is how the bacilli gain entrance into the system; for the prophylaxis against the disease depends largely upon its solution. It is generally held that they gain admission through the lungs by inhalation. This view has apparently been accepted without much inquiry as to its correctness, and even many interesting experiments have been performed to bolster it up, al-

though it is upon its face entirely at variance with the teachings of physiology and of clinical experience.

It is generally admitted that the bacillus tuberculosis cannot live in the air unless protected by some foreign substance, such as pus, or, in other words, that it cannot maintain its existence when isolated. Those who hold the theory that it is inhaled, claim that it gains admission through the medium of pulverized sputa, which is wafted about as dust. Now, the first question that arises is, can pulverized sputa be inhaled? or, to put it more precisely, can it be carried to the air cells or even into the bronchioles by the inspired air? A careful study of the mechanical construction and of the physiological conduct of the respiratory tract would lead us to believe that foreign bodies of any material size cannot readily be carried into the lungs by the air. It is a law of physics that a foreign body carried by the air will be deposited upon the first obstruction that can resist the force of the air that carries the body. Nature has laid obstructions in the way of foreign bodies all along the respiratory tract, thereby indicating that nothing was to enter that tract but air. The stiff hairs in the nostrils, the formation of the nose and pharynx, offering many surfaces for the impingement of foreign bodies, and above all the high sensitiveness of the mucous membrane lining the respiratory tract, whereby an expulsive effort is brought about the instant a foreign body touches it, are all safeguards against the introduction of foreign bodies into the lungs by means of inhalation. It is questionable therefore whether enough dried up tubercular sputa could be carried into the lungs by the inspired air, and if it could be carried in whether it would be allowed to remain there for a sufficient length of time to set up tuberculosis.

But even admitting that some pulverized dried-up tubercular sputa may pass all the barriers set up by nature and gain admission into the lungs with the inspired air, and having been deposited upon the respiratory mucous membrane, may resist all expulsive efforts to dislodge it, how will the tubercular bacillus get into the lung tissue? It will have to go in either by absorption or by penetration, for in most cases of tubercular inflammation of the lungs the disease is in the lung tissue itself and not upon the mucous membrane. If it enters by absorption it is taken up by the lymphatic system and carried into the circulation, thus taking a roundabout way to get into the lung tissue. If it enters by penetration it must first escape from the pus in which it has been imbedded, and as soon as it does so it is exposed to the germicidal influence of the air. In the event of either method of entrance it must, moreover, run the gauntlet of the phagocytic power of the blood. Now, considering the small amount of dried up tubercular sputa that can gain entrance into the lungs by inhalation, and the difficulties which the tubercular bacillus necessarily encounters in its efforts to get into the lung tissue and to establish a colony there, it looks very improbable that inhalation is the ordinary method by which the tubercular bacillus gains entrance into the system.

The inhalation theory of the tubercular bacillus is equally at variance with clinical experience. The fact that tubercular inflammation mostly begins in the apices of the lungs instead of in the base, the appearance of the disease primarily in the membranes of the brain, in the alimentary tract, in the pleuræ, and in bones and such glands as the ovaries and testicles, and the immunity of the many persons who are constantly exposed to inhalation of tubercular sputa dust, are all clinical phenomena which militate against the theory. If the tubercular bacillus gains entrance into the system by inhalation, we ought always to find the primary tubercular disease in the base of lungs or in the lymphatic glands. Of all parts of the lungs the apices are the least likely to become the receptacles of foreign matter by inhalation, first because of their inactivity, and second because of their position; so that when they even do become the primary seat of tubercular disease, the bacillus does not likely first get its lodgment there. The fact that the disease so seldom develops primarily in that part of the body in which it first gains lodgment would therefore bring us to the conclusion that if the bacillus tuberculosis gains entrance into the system by inhalation, it must do so by the absorption process, and if the bacillus is absorbed we have a right to expect the primary seat of the disease to be found in the lymphatic glands. If the inhalation theory were correct, everybody ought, moreover, to die of tuberculosis; for with the amount of dried up tubercular sputa that necessarily flies about in the air in street cars and in work-shops, it is difficult to understand how anybody can escape the disease.

But what about the experiments that have been performed in support of the theory, and which seem to demonstrate it beyond question or quibble? The most forcible experiments that have come to my knowledge are those of Koch, which consisted of rubbing up tubercular matter in water, spraying it into an enclosure, and compelling animals to inhale the spray. The animals all contracted tuberculosis, which result proved that when tuberculous matter is introduced into the system, tuberculosis results; but proved nothing more. The weak point in the experiments was that there was no precaution taken against the entrance of tubercular matter into the stomach. Spray readily condenses upon obstructing surfaces, and in these experiments considerably more tubercular matter must have been deposited in the pharynx and found its way into the stomach than was carried into the bronchial tubes by the inspired air.

Another theory about the manner in which the bacillus tuberculosis gains entrance into the system, and one which seems to have few believers is, that it gains admission through the stomach. Everybody apparently admits that it can gain entrance in this way, but few are willing to concede that this is the ordinary or usual way. Whether it is or not will, of course, remain for future experiments to positively determine; but physiology and clinical phenomena certainly seem to indicate that it is.

In the first place, it must be conceded that the alimentary tract is the ordinary avenue into the system for all extraneous matters. Its construction, machinery, and mechanism are all adapted to the ex-

peditious conveyance of matter from without the body into the body. Its purpose is to supply the body with food, and in health and the complete performance of its functions it is capable in a measure of discriminating against deleterious matter, or of rendering it innocuous. The stomach has the power of destroying animal life, and stands sentinel to all that enters the body; but only exercises that power when in possession of all its faculties. In the mechanical process of conveying food into the body, micro-organisms and parasitic animals of all kinds, either in the larval or developed state, likewise find their way in, and unless they are deprived of life by the stomach, will get into the system, seek out a congenial soil, and develop and reproduce themselves. In this way all parasitic animals which prey upon the internal organs of man, of which we have anything like definite knowledge, gain their admission into the body. Is it likely that the bacillus tuberculosis forms an exception? Certainly the stomach is the physiological way for it to enter.

Upon the theory that the bacillus tuberculosis gains entrance into the system through the stomach, the clinical phenomena of tuberculosis are quite intelligible.

From the days of Hippocrates it has been observed that the forerunner of phthisis is a disordered stomach. So close is the relation between the two diseases, that many have been led to look upon dyspepsia as the cause of consumption. The part which the stomach plays is, however, entirely a passive one. Because of its deranged condition, and its consequent inability to destroy the bacillus tuberculosis, the latter gains entrance into the system, by being allowed to pass unharmed into the intestines, being absorbed by the lacteals into the thoracic duct, and being carried with the chyle into the circulation. The bacillus in taking this course into the body, encounters no obstruction or difficulties after passing the stomach, at least until it encounters the blood corpuscles, and is well supplied with the necessary pabulum for its subsistence on the way.

The clinical facts that tuberculosis appears most frequently in the lungs, that its favorite site in the lungs is the apex, that in children it appears most frequently in the intestinal canal and the membranes of the brain, that its primary seat may be in the periosteum, the ovaries or testicles, the pleura, or, in fact, in any remote part of the body, can all be explained upon the theory that the bacillus gains its entrance through the stomach. The contents of the thoracic duct, after mixing with the venous blood, are first of all carried into the lungs; consequently, a larger number of tubercle bacilli enter the lungs, than any other organ or part of the body. It has been shown that the blood exercises a phagocytic influence over bacteria, hence, the farther the bacilli advance in the circulation, the fewer survive, and the more remote an organ or part of the body is from the entrance of the contents of the thoracic duct, the less its chances are of becoming infected with tuberculosis. The brain, the intestines, and the various organs in the abdominal cavity, probably receive the largest supply of arterial blood in the order mentioned, and, practically, receive it about the same distance from the entrance of the contents of the thoracic duct. We would, therefore, expect that the lungs, the brain, and the intestines, would be the most frequent seats of primary tuberculosis, in the order mentioned, and so we find them in practice. But the number of bacilli that enter an organ or part of the body, is not the only factor that determines the primary seat of the disease; the nature of the soil plays an important role. It has long since been recognized that anything which interferes with the free active circulation of an organ or tissue, predisposes it to tuberculosis. Hence we find the apices of the lungs, the congested membranes of the brains of teething children, the irritated alimentary canal of bottle-fed babies, the bruised periosteum, the thickened pleura, the congested ovaries, spleen, liver, and kidneys, becoming the selected soil for the development and reproduction of the bacillus tuberculosis.

It is also easily understood upon this theory, why so many persons who are exposed to tuberculosis, fail to contract it. The immunity is generally ascribed to improper soil, and whilst this may be part of the reason, it is not the whole reason; for it has been frequently proven by experiment on animals, that the disease will develop in any soil, if the bacilli are introduced in large enough numbers into the circulation. There are two factors in operation in the non-occurrence of tuberculosis in those persons who are exposed, first the bacilli-destructive power of the healthy stomach, and second the phagocytic power of the blood. Persons who have healthy stomachs, and who do not overburden them with too much or improper food, and who take sufficient exercise in a pure atmosphere to secure them a free circulation of well-oxygenized blood, will not contract tuberculosis, no difference what the exposure. To contract the disease it is necessary first, to be in such contact with infected persons or objects as to enable the bacillus to get into the stomach; second, to possess such a stomach as will, because of temporary or permanent disability to destroy the bacillus, allow it to pass into the circulation; third, to have in some parts of the body localized spots or a spot of torpid circulation, which offer a congenial soil for the development and propagation of the bacilli.

In my paper on the contagiousness of phthisis I have shown that some social relations between parties are probably necessary for the conveyance of tuberculosis from person to person, and that proximity of habitations and casual contact are in themselves not sufficient. It will not be difficult to understand, how tubercular matter finds its way into the stomach, if we for a moment reflect upon social customs. Because of the universal practice on the part of consumptives, of expectorating into handkerchiefs, or into open space, it is almost impossible to come in contact with them, or to remain for any length of time in a place occupied or frequented by them, without getting some bacilli into one's stomach. The lips and hands of consumptives who use handkerchiefs extensively, are necessarily smeared with tubercular sputa, and any persons kissing them, or shaking hands with them, can scarcely avoid conveying the disease

germ into their own stomachs, unless they wash themselves before partaking of food or drink. Drinking out of the same vessels and eating with the same utensils as consumptives, without prior cleansing; swallowing the dried-up tubercular sputa that is deposited upon the pharynx by the inspired air; the handling and serving of food by consumptives, such as that by waiters, cooks, grocers, fruiters, and milk dealers, suggest some of the ways in which tubercular matter may find its way into the stomach.

Whilst I do not wish to be understood that consumption cannot enter the system by way of inhalation, I claim that the stomach is the usual mode of entrance, and that there is ordinarily very little danger of contracting the disease through the lungs themselves. The part which inhalation plays in the etiology of the disease, is the mechanical part of carrying the tubercular sputa into the nares and pharynx, from whence it finds its way into the stomach. The whole question can, however, I think, be satisfactorily settled by experiment, and I hope at some future time to be able to illustrate what I have set forth in theory.

LUXATION OF THE FOURTH CERVICAL VERTEBRA RESULTING IN HEMIPLEGIA.

REDUCTION AND CURE.

By ERNEST LAPLACE, A.M. M.D. Paris.

Professor of Pathology in the Medico-Chirurgical College of Philadelphia; ex-visiting Surgeon to the Charity Hospital in New Orleans.

ALL injuries of the vertebræ are fraught with great interest to the medical profession, but none should claim our attention and deep observation more than those that result in pronounced functional disorder, and which under a rational therapeutic procedure have ultimately left no trace of their presence.

On March 17, 1889, while still visiting surgeon to the Charity Hospital in New Orleans, there was sent to me for consultation by a medical friend, a patient, George H., aged forty, a cotton-bale roller by occupation. While loading a ship with cotton-bales, one accidentally fell upon our patient's neck, crushing him to the floor in the ship's hold. He remained unconscious for six hours, and on regaining consciousness, the attending physician noticed that the patient's head was drawn considerably towards the left side, that it was immovable, and that there was complete paralysis on the left side of the body. The patient remained in this condition about two weeks, when he gradually recovered sensation and motion in the paralysed leg, but no improvement took place in the left arm. Electricity was applied for one month, but to no avail. There were tingling sensations throughout the limb, but scarcely any motion.

Two months after the accident, there being no further improvement, the patient was sent to me, and on examination the following condition was found: Anesthesia all over the left arm and ranging up the shoulder to the middle of the neck on the left side. Slight power of flexion in the fingers. Cannot, however, grasp anything. Evidences of slight atrophy in the arm and hand, the well-known glossy appearance being marked. There was considerable pain in the neck. This and the fact that the head was much drawn towards the left side, directed me to a more minute examination of the spinal column in the cervical region.

Beginning at the occipital protuberance and pressing with both thumbs, the underlying tissues appeared of a doughy consistence, and seemed congested. This appeared to extend as far down as the first dorsal vertebra. No fluctuation could be detected. There was one spot in the course of the cervical vertebræ which seemed much more sensitive, and this was over the fourth cervical vertebra. When pressing gently, but firmly, on either side of this point, a strange feeling of deep crepitation was detected. This was lost when looked for one inch above or below that spot.

We were naturally led to believe that there was a fracture of the spinous process of the fourth cervical vertebra, or perhaps of the transverse processes, and that the paralysis in the arm was maintained by the compression of one of the fragments against the spinal cord.

Having thus established the apparently real diagnosis, we proposed to the patient an operation to remove the compression upon the cord by extracting the loose fragments of the fractured vertebra. To this he readily acquiesced.

Being chloroformed. an incision four inches long was made in the middle line back of the neck, extending from the first to the sixth cervical vertebra, deep through the tissues to the spinal column, the parts were carefully retracted and the cervical vertebræ clearly laid to view, with all the proper aseptic conditions. It was then discovered that the spinous process of the fourth cervical vertebra was considerably to the right of that of the fifth cervical vertebra, and that whilst undergoing this luxation it had ruptured the posterior common ligaments and the capsular ligaments connecting these two vertebræ. There was no mobility of the spinous process, and no fracture could be detected. The patient's head was bent forcibly and by manipulation the luxated vertebra was restored to its normal position. The wound was disinfected with acid bichloride of mercury solution,[1] and closed with catgut sutures. Union by first intention was obtained and the dressing was removed on the eighth day.

From the day after the operation the patient's arm seemed to gain more mobility. Sensation also improved. This gain was constant and increased steadily until three months after the operation, when there was scarcely any difference between the function of the left and right, or uninjured arm. The remarkable history of this case and the gratifying results of the plan of treatment resorted to, offers the surgeon the following instructive points for consideration:

1. Before the operation improvement had taken place in the arm to a slight extent, but seemed to come to a sudden halt; this in connection with the traumatic cause of the disorder suggested the proba-

[1] Acid sublimate of mercury as a disinfectant, published from Koch's laboratory in 1889, in No. 40 of the *Deutsche Med. Wochenschrift*, by Dr. E. Laplace.

bility of some sort of compression existing upon the spinal cord.

2. The crepitus that was distinctly felt over the injured veriebra, proved to be due, not to fragments of bone, but to the friction of the overlying tissues upon ruptured ligaments; recalling to mind the false crepitus often felt over sprained joints, and due to the same cause as found to be present in our case.

3. The rapid improvement and cure resulting from the simple operation resorted to shows that, with the aseptic means now at the command of the surgeon, having established a plausible diagnosis he should be prepared to meet such an emergency with the resolute and radical surgical procedure that is indicated, at the same time exposing the patient to a merely insignificant danger by the operation.

MEDICO-LEGAL CASES.

By HENRY A. RILEY, ESQ.,
NEW YORK.

THE Maybrick trial in London has given rise to many comments on expert and other evidence, and also on the right of judges to instruct juries as to facts. It is the recognized province of judges to inform the jury about all law-points, and of juries to decide all questions of fact.

It seems that in the trial of Mrs. Maybrick Justice Stephen trenched upon the rights of the jury, and very likely caused the adverse verdict by so doing.

The following are some of the paragraphs of the Justice's charge: "Coming next to consider the alleged motive, it is not always possible or desirable to do so. In this case I am bound to say that there is evidence of a motive strong and disgraceful . . . That is how it stands, and how the matter of motive presents itself to my mind."

"Here was the man craving for the powder, begging to have it—no doubt he was in a terrible condition at the time—and the woman goes to get it, and when she gets it she does not give it to him. If the story were true, if they could accept it, it was a matter for them to decide; but they must take account of the imputations of falsehood made against her in those letters. In that state of things was it natural that an affectionate wife should all of a sudden give way to that which her sick husband suggested, and do so extraordinary a thing as to put an unknown powder into her sick husband's meat-juice? This was a point which pressed hard upon her."

In concluding his charge, Justice Stephen said: "There was no doubt that the propensity which leads persons to vices of this kind did kill all the more tender, all the more manly, or all the more womanly feelings of the human mind.

"That was a comment upon which he would not insist. He would spare them what would be painful to him, exquisitely painful to her, and not necessary to them. He could not say anything about it except that it was easy enough to conceive how a woman in so terrible a position might be assailed by some fearful and terrible temptation. When they took that into account, they must look to some extent at the feelings which were shown, and which the evidence showed remained in her mind."

These expressions and others in the charge bore so heavily on the unfortunate woman on questions of fact, that it is difficult to see how the jury could have failed to be impressed by them; and if they were, just to that extent did the Justice exceed his privilege. It is partly on account of the evident prejudice in the mind of Justice Stephen that there has been such an outcry, both in England and this country, against the verdict, an outcry which has been at last effectual in securing a commutation of the sentence of death to life imprisonment.

THE ALABAMA SUPREME COURT has decided that the conclusive test as to the character of bitters and ordinary liquors was the general use to which they were put, whether as a medicine or beverage.

In the case at bar, the article contained twenty per cent. of alcohol, and eighty per cent of herbs, barks, roots, water, etc. If it cannot be used as a beverage, if the other ingredients are medicinal, and the alcohol is a necessary preservative or vehicle for them, the sale is lawful.

The court quoted with approval a decision in Kansas, where it was said: "There may be cases where the *bona fide* use of a moderate quantity of spirituous liquor in a medicinal tonic would not alone bring a beverage (or decoction) within the statute."

The Kansas statute prohibited the sale of "all liquors and mixtures, by whatever name called, that will produce intoxication." It is not held to embrace standard medicines and toilet articles not ordinarily used as beverages, such as tincture of gentian, bay rum and essence of lemon, although containing alcohol.

Whether it embraced certain cordials or bitters was held to be a question of fact dependent on the evidence as to their intoxicating qualities and ordinary use.

If the compound or preparation be such that the distinctive character and effect of intoxicating liquor are gone; that its use as an intoxicating beverage is practically impossible, by reason of the other ingredients, it is not within the statute. The mere presence of alcohol does not bring the article within the prohibition. The influence of the alcohol may be counteracted by the other elements, and the compound be strictly and fairly only a medicine. On the other hand, if the intoxicating liquor remain as a distinctive force in the compound, and such compound is reasonably liable to be used as an intoxicating beverage, it is within the statute, and this though it contain many other ingredients, and ingredients of an independent and beneficial force in counteracting disease or strengthening the system.

A similar doctrine has also been proclaimed in Mississippi. The article sold there was "Home Bitters," a decoction composed of thirty per cent. of alcohol, and the rest of water, barks, seeds, herbs, and other like ingredients. It was alleged by the defendant to have been sold as a medicine. It was held that if the compound was intoxicating and was sold as a beverage, the jury should convict; but if it was sold in good faith only as a medicine, they should acquit.

The courts in Massachusetts and other States have had similar decisions, and the prevailing doctrine is

that, where there are prohibitory or license laws, it is a question for the jury to decide whether any particular article is a medicine or a beverage, and its general character and use is the criterion by which to decide.

THE QUESTION of the advisability of capital punishment is one which never seems to be finally settled. Some states and countries have abolished it for half a century, and find the change a desirable one, others after a short time of suspension return to the old method of punishment. It is less than a century since there were in England about one hundred different offences for which death was the penalty; now, perhaps only murder, arson and treason require the severest punishment known to the law. The Albany *Law Journal* is a firm disbeliever in the efficacy of capital punishment to check crime, and furnishes some statistics taken from different countries to prove the point. They are as follows: "Holland: Capital punishment abolished September, 1870 (as a matter of fact there has been no execution since 1860). The statistics of murder were as follows: 1861-9, 18 murders; 1871-9, 17 murders; and this notwithstanding an increase of population. Finland: There has been no execution since 1824. The judge of the Court of Appeal says: 'The security of person and property has not been in the least diminished by the suspension of capital punishment. Murders are extremely rare.' Switzerland: In 1874 capital punishment was abolished by the Federal Council. In 1879 Cantons were allowed to choose for themselves and two or three have elected to re-instate the death penalty. Belgium: No execution since 1853. In the ten years before 1863, 921 murders; in the ten years after 1863, 703 murders. Prussia: In decade 1869-1878, 484 persons sentenced to death, only one execution (Hödel). Portugal: Capital punishment abolished. Roumania; Capital punishment abolished. Tuscany: No executions for fifty years. Russia: Capital punishment only retained for treason and military insubordination. America: Michigan, capital punishment abolished in 1847; Rhode Island, 1852; Wisconsin, 1853; Iowa, 1872; Maine, 1876. In Michigan the statistics show that since 1847 murders have decreased, relatively to the population, fifty-seven per cent. As to Wisconsin Governor Washburne writes in 1873, 'It is twenty years since the abolition of capital punishment. No State can show greater freedom from homicidal crime. With a population representing almost every nationality, statistics show that crime instead of increasing with the growth of the State has actually diminished. Of Iowa Senator Jessup writes in 1876: 'Murder in the first degree has not increased, but for four years decreased. Previous to the repeal of the old law there was one murder for every 800,000 people. For the four years since abolition there has been one in every 1,200,000; There is more lynch law where the gallows is retained." The statistics given above are not in all cases the most recent, but it is not known that later experience has changed them. In the majority of the United States capital punishment is inflicted, and there is no special public sentiment against the practice; there is, however, as in New York, a feeling that hanging is not the best method, and a law has been passed making an electric shock the only legal death penalty. There has been no instance yet of the application of this new method of execution, and it cannot be said what public sentiment really is in regard to the substitution. It does not appear, however, that the people wish to have capital punishment abolished.

THE QUESTION whether an accident insurance company is liable on a policy where the insured kills himself, when insane, has now been so frequently before the courts that the law is settled in a large number of the States. The companies have very frequently set up the contention that they could not be held liable, and in some instances they have been successful. In most of the States, however, the courts have held with great emphasis that the companies must pay the policies. In a recent well considered case in Michigan this was the opinion of the court, and the doctrine reiterated that though a person kills himself, yet the mode of death is "external, violent, and accidental" as named in the policy, provided the person is insane.

This is the rule in Michigan, Maine, Georgia, Louisiana, Minnesota, Pennsylvania, Vermont and probably other States. The opposite principle of non-liability prevails in England, and in this country in Massachusetts. In New York a distinction has been taken between the two views, and it is held that impairment of mind so that a person is not conscious of the moral character of the act is not in itself sufficient to throw a liability on the company, but that the person must be so insane as not to know that his act will cause death or else he must be under the influence of some insane impulse which he could not resist.

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL.

CHOREA.

YOU will doubtless remember, gentlemen, the case of chorea, or rather hemi-chorea, which I showed at the clinic of last week. To-day I bring the little girl before you again, that you may observe the improvement in her condition, and to add a few remarks to what has already been said. Although the question as to which side of the body chorea occurs more frequently upon is as yet not positively settled, most authorities agree that it is more common on the right side. This child, you may recollect, was ordered Fowler's solution in three-drop doses, resulting, as you notice, in a lessening of the symptoms, which were not in this case primarily aggravated by the arsenic, because of the latter being administered at so long a period as one year after the outset of the affection. We shall increase the dose of the solution to gtt. iv, until toxic effects are noticed, when the amount of the drug shall be halved, but not wholly withdrawn from the patient, as is sometimes erroneously done.

ENTERO-COLITIS.

I shall devote considerable of the hour to-day in speaking to you about entero-colitis. This disease is the scourge among the children of our large cities in summer; and, therefore, to discuss it with you at this time will be quite opportune. To begin with, the morbid anatomy of entero-colitis is, as you may infer. an inflammatory hyperæmia of the small and large intestines, but confined principally to the ileum and colon, while it is usually most intense at the ileo-cæcal valve. The mucous membrane is reddened, swollen, and softened. The redness may be confined to the injected bloodvessels and solitary glands, giving an arborescent appearance; or, the latter becoming prominent and more opaque than natural, renders the effect similar to that which would occur on sprinkling white sand over the membrane. Peyer's patches, also, become opaque. The swelling at the ileo-cæcal valve often prevents the passage of the intestinal contents; and some contend that vomiting is thereby induced. Again, not rarely we find the mesenteric glands enlarged, and blood vessels injected. The causes of entero-colitis are four-fold, namely: improper feeding, age, season of the year, and locality of residence. The disease is rare in winter, and in sparsely-inhabited districts. Children subjected to extreme changes of temperature, as living in hot rooms, situated in crowded parts of a city, then exposed to drafts from without, easily acquire this dangerous trouble. About the middle of May, or June 1st, its prevalence becomes first marked, whilst during July and August it almost assumes the proportions of an epidemic. Temperature alone does not, as some would seem to suppose, account for the affection; but over-crowded sections of our large cities, where the cubic air space *per capita* is greatly deficient, filth and degradation, undoubtedly are equally potent factors in the etiology. Between six and eighteen months of age infants are more liable to entero-colitis than before or after that period, which, it will be seen, is that of teething, when a sympathetic influence is presumed to predispose to the inflammation of the bowels. However, it may be remarked here that the time of first dentition is not nearly the bugbear to physicians as formerly it was. Finally, the ingestion of sour milk and of large quantities of starchy food by children are frequently important causative agents in this disease.

The symptomatology of entero-colitis is important. At first the child becomes fretful and peevish, crying in its sleep; the head and palms of the hands are hot; anorexia, pallor, and eructation of acid substances occur. Vomiting which may become very troublesome, is also common; diarrhœa is, of course, marked. The stools should be studied from day to day with closeness and care. At first semi-solid, yellowish, and neutral in reaction, they are called homogeneous; in a day or two or three they assume a greenish tinge, are neutral to acid in reaction, and hard, yellowish or yellowish-white masses, which are acid in reaction, may be seen floating about. In very severe cases we are apt to have offensive, watery discharges. Thus, by examining the stools, the stage of the disease may be readily ascertained. Not infrequently, slime and blood, ropy, mucoid, blood-streaked masses are passed from the rectum. The tongue is coated yellow, is dry and red at the tip and edges. Although the temperature is seldom higher than 102°, nevertheless it is continuous in range for three or four days afterwards, becoming remittent in type. Rapid and full pulse, a few days later, becoming small and feeble with about 120–140 beats per minute, is associated with the fever. When a fatal termination is pending, nervous symptoms, and restlessness, sometimes convulsions (usually unilateral), with a very dry skin, frequent discharges of feces, and all the evidences of collapse may be manifested, in one class of cases; while on the other hand, there may be a disposition towards morbid quietude and profound drowsiness, the eyelids being often *open*, along with a cessation of the diarrhœa and vomiting; yet, strange to say, the child may die on the following day. Should the child enter convalescence, it will be observed to take more interest in its surroundings, the vomiting and diarrhœa cease, whilst thirst diminishes considerably with the subsidence of fever. As this malady tends to become chronic, the prognosis must be always guarded. Nor should we hesitate to express, when necessary, an unfavorable opinion, as a sudden termination is not unlikely at any time, especially if the case be a severe one, and nervous symptoms be observed, or if progressive emaciation and a non-yielding to treatment, after two weeks' trial, are noticed.

The hygienic management of entero-colitis in children is fully as important as the medicinal treatment. To lessen the virulence of the trouble, and to favor a speedier cure, it is plainly our duty to recommend a change of air—residence at the mountains or sea-shore, if possible, although the patient should not be fatigued by too long a journey. When the parents cannot afford such change for their children —which is commonly true of these cases—the little one might be taken to a park daily; or, better still, it may be given a ride daily on a river steamboat, so as to interpose breathing spells of an uncontaminated atmosphere; and though these efforts may seem trifling, beneficial results will invariably succeed.

Bathe the child two or three times daily with sponge and water of 80° F. When there is a tendency to collapse, a general warm bath, under the supervision of the doctor or nurse, will be found to be an efficient stimulant. Mothers should feed their own babies, if possible, but not too often, as the milk has been found to be of an inferior quality when given more than once every two hours. If a wet nurse must be procured, the physician should select her himself after a rigid and careful examination, noting her moral character and health; all evidences, however slight, of constitutional taint, whether hereditary or acquired—especially syphilitic or scrofulous—should positively exclude a woman from being employed as wet nurse. Some women are refused when their milk is older than the child to be suckled; but if the milk is of good quality, we should offer no serious objection to their employment. Sterilization of cow's milk must be resorted to when the child cannot get along well with its mother or a wet nurse.

Boiling the milk for at least ten minutes is essential, to completely sterilize it. It may also be sterilized by bottling, and immersing it into boiling water for thirty minutes. Most artificial foods, which are used to a great extent at present, have for their basis cow's milk. They are often unsuccessful, and numerous chemical analyses have shown them to vary in composition from time to time; hence they are unreliable. We should be able to do without them and prepare cow's milk so that the proportion of its constituents may as nearly as possible approximate those of human milk. The formula of Dr. Arthur V. Meigs, as modified by Dr. Rotch, is well adapted for this purpose, the ingredients and their proportions to make one pint, being about as follows:

R.—Cow's milk . . . . . f℥ij.
Cream . . . . . f℥iij.
Water . . . . . f℥x.
Milk sugar . . . . . ℥vij.

Mix these together in the morning, sterilize, and render alkaline by adding f℥j. of limewater to the pint, and use during the day. Mild purgatives, such as the aromatic syrup of rhubarb, or castor oil, are indicated at the beginning of this complaint. Then, alkalies and mild astringents should be exhibited, as in the form of the following powder, for example:

R.—Cretæ præparat . . . . . gr. v.
Bismuthi subnitrat . . . . . gr. iij.
M. ft. chart.—Sig. One every hour.

When the fecal discharges become green, there is greater necessity for alkalies, combined with small doses of an opiate, thus:

R.—Tr. opii deodorat . . . . . ♏ ¼.
Bismuthi sub-carb. . . . . gr. iij.
Mist. cretæ . . . . . f℥j.
M.—Sig. To be given at a dose, every two hours.

In the event of offensive stools, calomel, about one-twelfth grain, is an invaluable remedy, and may be given, in combination with the prepared chalk and some aromatic powder, once in every two hours for about forty-eight hours, when, if no change is effected, it is useless to continue its administration. Should powerful astringents be desired, the diluted aromatic sulphuric acid, with liq. morph. sulphat., may be tried cautiously. Injections of laudanum and starch-water; nitrate of silver gr. j, or sub-nitrate of bismuth gr. iv or v to half an ounce of gum arabic water, and enough plain water to make f℥j may be used, as an enema, when drugs are not well borne by the stomach. When convalescence has been established, pepsin and dilute hydrochloric acid, or comp. tincture of cinchona, should be prescribed to hasten resolution and tone the system.

ENDOCARDITIS.

We will now consider briefly the diagnostic features of this boy's present complaint, which started a week ago with chills, followed by fever and embarrassed breathing. To determine the nature of his affection, a physical examination of the chest is clearly indicated. On inspection, we notice first the area of the cardiac impulse to be slightly increased; the force of the beat is apparently exaggerated and duplex in character, the ventricles evidently not contracting simultaneously. Palpation corroborates this view, for the heart contracts in an almost tumultuous manner. At the same time, it is observed that the apex beat is in the normal position, relatively, and hence we infer that no enlargement exists. We can account for the augmented force of the heart-beat and the appreciable systole of the right ventricle by the plausible supposition that the blood does not circulate freely through the lungs; therefore, the right ventricle has an excessive amount of work to perform, and is put to the strain. Auscultating over the region of the base and apex of the heart, successively, we hear a murmur, which in this case is transmitted as far as the left scapula.

From the previous history of the patient we glean the facts pointing to an attack of sub-acute rheumatism one year ago. That there was no endo-carditis at that time, we do not doubt in the least, since there is no cardiac hypertrophy here to signify the chronic valvular trouble which must have engendered it. Hence, we conclude this to be a case of acute endocarditis. In this disease, the murmur is always systolic in time, and, as a rule, can be heard only in front; but, as to locality and quality, it may be said that all sorts of murmurs are audible at various times. Before the systolic murmur is established fairly, many adventitious sounds—scratching, rasping, etc.—or an accentuated second sound may be heard; but the systolic murmur alone is diagnostic, in conjunction with the other physical signs, and should be listened for carefully, as its position may change from hour to hour and day to day.

—*Prof. J. M. Anders, M.D.*

TREATMENT OF HEMIPLEGIA.

For a case of hemiplegia of three months' standing, Waugh ordered mercury to be given in doses just below the line of toleration. He considers it the only really efficient means of procuring absorption of the clot and inflammatory products, when absorption is indicated, as at present.

The question of restoration of the function of nerve-fibers, now inhibited, comes later; when they have been relieved from pressure. The indications in treating a hemiplegia are, first, rest, to limit the danger and allow a clot to form; second, to keep down the resulting inflammation; third, to relieve pressure by causing absorption; and fourth, to restore to activity nerve-fibers, temporarily inhibited, by the use of electricity and strychnine. The final indication, that of repairing nerve-fibers actually broken, is one which we have no therapeutic means of fulfilling. Nature may in time bring about repair, especially in the nerves of the extremities; but it is extremely doubtful if she ever does so in the nerve-centers. In fact, it is the rule that after a hemiplegic attack the patient may recover most of his motor power, but he never recovers all.

LARAMÉE asserts that the convulsions of uræmia are, so to say, concentrated more than in the other convulsive diseases.

THE IMMEDIATE CAUSATION OF LABOR.

FROM the earliest times this subject has been the *quæstio vexata* among physiologists. Some have attributed the termination of pregnancy and the beginning of labor to one cause, some to others, and not a few to a whole group of causes dependent upon certain conditions, both of the fœtus and of the mother's genital organs. Up to the present time no single theory has been accepted as the true explanation. Barnes holds that some change in the fœtal circulation produces a corresponding change in the mother's, and so institutes the process of labor. The views of Drs. Power, Depaul, Dubois and others in regard to the sphincter action of the cervix uteri and the reflex action of the latter upon the uterine walls as the ovum descends and comes in contact with it about the latter months of pregnancy, are probably those most generally adopted, though they are surrounded by more or less valid objections. Extreme distention of the uterus, advanced as a cause by Dr. King, fatty degeneration and gradual separation of the decidua, proposed by Sir James Simpson, and the ovarian theory of Tyler Smith, have each been objected to as not sufficiently plausible or scientific. Lusk temporizes by grouping all the causes in the order of their relative frequency thus; with the advance of pregnancy, the uterus becomes more irritable, the decidua less firmly attached, the carbonic acid increased in amount in the blood, the circulation more easily disturbed, the emotions and sensibilities more readily excited, and the ovum more like a foreign body requiring its own expulsion. Tarnier, without attempting to arrange them according to their relative significance, also collects a group of causes, chief of which he cites the development of the uterus at the end of the ninth month, the hypertrophy of the muscular fibres, the increase of the uterine, nervous and venous symptoms, the obliteration of the neck of the womb, the separation of the decidua membrana at about the level of the cervico-uterine canal, the direct contact of the fœtal membranes with the external os, and the repeated energetic movements of the fœtus itself. The chief factors, therefore, in the production of labor, as explained by this author, are irritability and reflex action. On the other hand, Prof. Garimond, of Montpellier, gave as his theory, so recently as last year, the single cause, irritation of the uterus at all points of its internal surface by the growing fœtus.

After all it seems we must admit our ignorance in regard to one of the commonest of physiological phenomena, for here, as in all other departments of science, the simpler the phenomenon, the more difficult often is the explanation. The action of gravitation, and the transmission of light, were everyday occurrences, and yet how long before any explanation of such common facts was afforded! It all appeared so plain and manifest that a mere figment of the mind propped up by a few specious arguments was accepted in lieu of experimental demonstration.

The question as to the immediate causation of labor belongs to this category of commonalities. It has been settled more by argument than by long and close observation. The general consensus of opinion is that irritation of the uterine nerves probably enters as the most important factor; but having scaled this first obstacle, another is encountered in our advance to the proper solution. What is the immediate cause of this irritation, and what is its *modus operandi?* Is the irritability simply a physical process dependent upon the enlarging fœtus, becoming, as it were, a foreign body, and by reflex irritation causing its own expulsion, or is it a chemical one dependent upon certain irritative changes in the blood, and the circulation? Most authors give special weight to the former statement of the case. Then, again, is there any change in the motor nerve centers of the medulla, or in the uterine nerves themselves to give rise to the heightened excitability? Such are a few of the questions still awaiting a satisfactory answer which is founded upon exact experimental research.

In the August number of the *Archives de Tocologie*, Dr. Girin, of Montbrison, published a long and exhaustive paper, in which he accepts the irritability hypothesis, believing that the gradual descent of the fœtus within the uterus, and its final contact with the sensitive surface of the cervix is the origin of the whole process of labor. The originality about the author's paper is the way in which he explains the regular, periodic descent of the fœtus, and its corresponding induction of labor at about the same, regular, fixed time. Basing his arguments upon the experiments of Preyer, Buniva and Vauquelin, Labruhe, Pinard, Gauthier, Mya and Graziadei, in regard to the comparative densities of the fœtus and amniotic fluid, showing that the latter diminishes while the former increases, he asserts that the beginning of labor is dependent solely and primarily upon the

principle of Archimedes. This is, then, the immediate cause in determining labor, and is purely a physical and mechanical one.

The density of the amniotic fluid attains its maximum during the earliest months of pregnancy, and can reach even as high as 1.030. At term it had reached its minimum, and is then but little above unity.

The density of the fœtus, on the other hand, is below or about equal to that of the amniotic fluid during the earliest period of pregnancy. The fœtus at this time is a true floating body, but its density gradually increases with the contamination of pregnancy in inverse proportion to that of the amniotic fluid. Pathological changes or improper development in either the amniotic fluid or fœtus, can therefore be cited in the majority of cases as explanatory of miscarriages or abortions not traumatic in origin. This is a simple explanation of the induction of labor and on the face of it exceedingly plausible. The author's paper contains reliable statistics and is full of close, sound reasoning. Further proof is needed, however, and if it be forthcoming, a most important factor will be obtained in explaining the immediate causation of labor in health, and in many diseased states.

—L. H. M.

A FEEBLE STEP.

A FEEBLE, yet not uncertain, step in advance has been made in the interest of higher medical education, by the recent law, passed by the New York State Legislature, entitled, An Act to Provide for Preliminary Education of Medical Students. A copy of this law has recently been sent to the physicians of the State, together with the rules adopted by the Regents of the University of the State of New York for the examinations, and the places and dates appointed by them.

The examinations are in arithmetic, geography, orthography, English grammar, American history, rhetoric, English composition and elements of natural philosophy. The candidate is expected to have a thorough knowledge of the whole of a standard text-book on each of the required subjects, but cube root will not be included in the arithmetical examination. Seventy-five per cent. of correct answers is required in all subjects except orthography, in which eighty-five per cent. is required. After successful passage of all examinations the candidate will receive a "medical student's certificate."

The enforcement of this act will, at least, prevent the entrance into the profession of men who, debarred by lack of an ordinary education from other pursuits, have hitherto sought refuge in medicine. Indeed, the very fact that the "powers that be" are at last aroused to the crying need of protecting the people, by standing guard at the very portals of medical education, is a feeble but nevertheless happy augury of higher efforts in the future.

The glimpses we occasionally receive (from publications of some of our State Boards of Examiners) into the fearful state of ignorance of their candidates, have caused us to blush for the recklessness with which some of our colleges have conferred degrees. Our lawmakers, once made alert upon this point, will be more readily impressed when we ask further safeguards to the public. Nothing short of a strict examination, by a competent State examining board, which is independent of all colleges, will afford the public complete protection.

MILK SICKNESS.

MEDICAL works, as a rule, are written by men who have acquired their experience in great cities, hence they are frequently wanting in the description of affections confined more or less to the rural districts. Milk sickness, known sometimes as simple "sick stomach," "tires," "swamp sickness," "slows," "river sickness," "bilious sick stomach," and "puking fever," is an apt illustration of this truth. Scarcely any of our leading medical authorities even so much as refer to it and yet it is among the most alarming and rapidly fatal of all diseases, unless promptly recognized and treated.

Dunglison states that milk sickness is occasionally observed in the states of Alabama, Indiana and Kentucky, to which Dr. W. M. Tuller, of Bowling Green, adds Ohio and Illinois. The latter recently read a paper, based upon his own experience in the treatment of this disease, before the Northwestern Ohio Medical Association, and has published it in the September number of the *North American Practitioner*. He claims that milk sickness is quite as common in man as in cattle, owing to the farmers' habitual use of milk and butter. It is not dependent upon the drinking of impure water as is commonly stated. In this respect the author differs entirely from Dr. Joseph Sager, of North Washington, O., who read a paper upon the same subject before the same society a number of years ago. The poison is in all likelihood vegetable in origin, as indicated by the following facts:

1. The disease prevails to a much greater extent in dry seasons when forage for animals is scarce, and they are obliged to sustain themselves, not on what their appetites dictate, but on what they can get.

2. It is never known to occur in animals that are confined on tame pasture.

3. In timber and wild land where animals have been known to be poisoned while feeding, not only for one season, but year after year, as soon as this land is cultivated, the disease disappears.

4. The disease only prevails during the summer and autumn months, the season of the year when vegetation flourishes. The particular kind or species of vegetation that contains the poison has never yet been determined, and yet a botanical description of the various plants that have been accused by the profession and laity, of producing the disease, would be quite voluminous.

Sheep seem to be more susceptible to the poison

than cattle, while the horse and fresh milch cows seldom if ever show any signs of the disease.

The poison is neurotic in its operation as shown by the character of the symptoms. For several days before the attack there is excessive languor, loss of appetite, nausea, pallor and constipation. If no relief be afforded, the patient soon goes to bed and lies on his back most of the time. Vomiting sets in and is both violent and persistent; the constipation becomes more obstinate. Next follow the special nervous symptoms. The patient grows exceedingly restless, tosses his limbs about, sighs occasionally, and becomes partially or wholly unconscious. If consciousness remain, extreme heat of the body, and great thirst are complained of. The temperature remains normal or becomes depressed; the pulse continues normal but strong; the pupils are unchanged or slightly dilated; the abdomen flattens; and the heart and large bloodvessels beat violently. The matter vomited consists first of ejecta, then of a glairy substance like mucus and finally bile, either dark or natural in color. In most cases there is a peculiar pathognomonic odor, not inaptly described as the "smell of rising used in making milk or salt-rising bread."

This disease is of short duration, terminating in recovery or death in three to fourteen days. Its diagnosis is easy and only liable to be confounded with acute gastritis, cerebro-spinal meningitis or obstruction of the bowels.

To eliminate the poison, stimulate the nervous system, and sustain the vital powers, are clearly the indications for treatment.

Dr. Tuller himself lays most stress upon early and free purgation. For this purpose nothing answers so well as calomel, given in severe cases in thirty and forty grain doses, repeated every four hours until the patient is thoroughly purged. This treatment should then be continued for three or four days, but with smaller doses of the calomel, only sufficient to cause three or four evacuations *per diem*. It is useless to give small or even average doses of the calomel, and the ptyalism which occasionally follows these massive doses is insignificant in comparison with the advantage gained. Usually the vomiting ceases and convalescence begins after the first free purgation.

For the nervous system strychnine and nux vomica, by the mouth or rectum, are the stimulants to be employed. Alcoholic liquors, so easily borne in milk sickness, have also proved most beneficial. Simple enemas, to aid catharsis and for purposes of nourishment, should also be remembered. Such remedies as bismuth, and oxalate of cerium to allay the vomiting are worse than useless, merely causing loss of valuable time. Prophylaxis, of course, consists in abstinence from milk or meat of animals known to feed on dangerous lands.

PROF. FOUCHER says that certain amblyopias are caused by uterine disorders.

Annotations.

DR. MANGIN has just published an interesting article in the *Marseilles Médical* upon the important question of catarrhal salpingitis. The following is his treatment: In the acute period of the disease, absolute rest in bed, very hot vaginal injections, ice to the stomach, according to the gravity of the symptoms; morphine, chloral, bromide or antipyrine; removal of all constriction about the abdomen and the use of revulsives. In the chronic period, medical or surgical treatment is recommended. The first named consists in combating the dangers of pelvic peritonitis by the use of hot antiseptic vaginal injections. For the inflammation of the cervix use tampons of wadding medicated with glycerine and iodoform, inter-cervical and intrauterine applications of sticks of iodoform. Add to this the administration of bitters and tonics, the use of hydrotherapy and thermal treatment (St. Sauveur, Neris, Plombieres, Luxeuil, etc.) The surgical treatment is either palliative or curative. The first is for the endometritis cervicitis and the prevention of the discharges. Careful curetting of the uterine cavity, removal of the diseased parts of the cervix and the dressing of the wound when these are removed, are the measures to be adopted. If there are old adhesions fixing the uterus in one position, they should be broken up under chloroform. In other cases, after having washed out the uterus, and freed the orifices of the tubes of any fungous growths which may almost completely obstruct them, dilatation of the uterus and drainage should be practised. Finally, the dernier resort is laparotomy and removal of the Fallopian tubes; but this operation ought never to be performed except after most careful consideration.

THE bogus diploma mills of Vermont and New Hampshire are being rapidly unearthed by the public authorities, The "Trinity University, of Burlington, Vt.;" the "Vermont Medical College, or Second Medical College of the American Health Society for Scientific and Benevolent Purposes," institutions whose very existence was unknown, have been found to possess articles of incorporation. The laws of Vermont are so lax in this respect that application for these articles may be simply made to any town clerk and they are forthwith granted. Thanks are due to various physicians in New York, Vermont and New Hampshire for exposing these audacious imitators of the once notorious Buchanan.

A reputable Philadelphian has just been acquitted of a charge of felonious assault preferred by a young woman. At the conclusion of the evidence Assistant District Attorney Boyle said that he could not conscientiously ask for a conviction in this case.

This is all very well, as far as it goes, as none of Dr. Regar's numerous friends thought for one moment that he was guilty. But to whom is he to look for recompense for the loss of esteem and the expense

consequent upon being called upon to answer such a charge? The hope of blackmail, the wish to hide the results of indiscretion by accusing an innocent person, or mere hysteric prurience, occasions these charges, the evil effects of which may cling to a man for a lifetime. The law should provide means for preventing this wrong, which is not susceptible of reparation, by compelling the plaintiff to produce sufficient proof to warrant the charge, and to give security for the costs and damages if she fails. Many persons would avoid a physician who has been the victim of such an attack, although there may not have been any excuse for it; and thus the wrong done is too far-reaching to be measured and assessed.

UTERINE CATARRH—LOCAL APPLICATION OF MORPHINE.

REASONING upon the pathological findings, V. Siviecceki concludes that as the uterine mucosa is strongly hyperæmic, swollen and puffy, with increased secretion, a rational treatment demands removal of these conditions. Dr. S. recommends morphine, basing it upon the recorded case by Levinstein of atrophy of the uterus produced by morphine habit which was removed by withdrawal of the morphine. He demonstrates the result of treatment by reference to twelve cases, of endometritis with uterine catarrh, in which he applied a solution of morphine containing five mgrm., three times a day to the cavity. The treatment lasted three to four weeks. In seven cases improvement ensued; in four, complete restoration. Only in one case it failed; being probably gonorrhœal, yielded to chloride of zinc. Of course, this treatment is ineffectual in chronic interstitial endometritis, in which the former granulation tissue has been converted into cicatricial tissue. In these cases, curetting, followed by tincture of iodine or pure carbolic acid is still the most rational procedure.

THE treatment of typhoid fever by cold baths, which has been the subject of several articles in our special column on Hydrotherapeutics, is the theme of a paper by Dr. J. H. Hunt, in *Gaillard's Medical Journal* for October. After some very pertinent and judicious remarks on the unfounded prejudices existing in the professional and lay mind against cold bathing, Dr. Hunt details his fifteen years' experience in it. The mortality, in the first years of his professional life, under expectant and sympathetic treatment was but 21.05 per cent., while in the series treated by the systematic cold bath the mortality was 5 per cent. He dwells upon the necessity of early and strict bathing, "even before the actual necessity exists."

This paper, together with that of Dr. Smythe, of Indianapolis, are the first clinical resumés which have appeared since our agitation of the subject, and they are, it is hoped, an entering wedge to the popularizing of this life-saving method of treatment.

A WHOLESALE drug-house offers an inducement to any one who will invent a powder that will exterminate humbugs.

Letters to the Editor.

NOVEL DESIGN FOR TREATMENT OF FRACTURED CLAVICLE.

THE diagram here attached will illustrate a novel design for treating fractures of the clavicle.

A represents a round piece of steel or iron, made in a circle two and a half inches in diameter, with a shank seven inches long, with a thread cut to screw into B, shaped like a crutch head, and padded to fit in the axilla. C is a piece of webbing or leather, with a buckle affixed to C. D E and F are like straps also provided with a buckle.

To adjust the appliance in case of fracture, the crutch head is placed under the arm of the injured clavicle, and the ring A lying flat against the chest walls under the nipple below or over the attachment of the fractured muscles. The straps C D are then properly adjusted and buckled over the opposite shoulder. Then the straps E and F are fastened around the body under the opposite nipple.

These straps can be made of adhesive plaster, and secured to the skin so that there can be no slipping, or the leather or webbing straps can be secured in like manner.

This appliance was first used by the late Dr. Washburn, of Wilkesbarre, Pa.

The system as to the use of adhesive appliances is my own.

This little novelty has the advantage of keeping the fracture well under control, and can at the same time, while fulfilling all the indications in treatment, be worn under the clothing out of sight. For one instance, that of a druggist, a patient of Dr. Ross, of Wilkesbarre, the arm was used in compounding, and other duties of his business, during the whole of the treatment, and as good a result was obtained as is usual under other and more cumbersome methods.

S. W. TRIMMER, M.D.

WHITE HAVEN, PA.

A CASE OF CRIMINAL ABORTION.

EMMA R., aged twenty-three. While standing on a chair picking apples, the chair turned and let her fall to the ground on a piece of wire about size of No. 20 catheter, French scale, which entered the vagina and into the os uteri, from which she tried to remove it but failed. The part extending beyond the os she cut off. There was some hemorrhage during the night. In the morning, August 15, she walked

two miles to her home, and two miles from her home to see a doctor, making in all four miles. The doctor tried to remove the wire but failed. He put her in his buggy and brought her to my office, four miles further. The woman had a very slightly increased temperature, but no pain.

On examination I found an extensive laceration of the cervix, which had been of long standing. The wire had entered the body of the uterus posterior to the internal os, barely reaching the external os. I used my fingers to remove it, but failed. I then used a pair of strong forceps, and removed the wire. It was at right angles with the sides of the uterine canal, of a rectangular shape, and two and a half inches in length.

There followed a considerable hemorrhage after the removal. The body of the uterus was four inches in length, and the uterine canal one inch at the fundus. There was retroversion, but no laceration of the vagina. The patient had had one child at seven month's term.

After they had gone a few hours, I telephoned to the doctor, telling him to be on the lookout for an abortion, as I expected there was some special reason for the wire to be in that position. He took her home, gave her quinine, grs. 20, but could not prevent a rigor. Temperature went up to 103°, but by August 16 it came down to 101°, and finally to normal. The doctor watched the patient, and told the nurse to do so, and on August 15, in the evening, the fœtus, with secundines intact, was found in the discharges from the vagina. The doctor accused her of a crime, and she admitted having placed the wire there, and that it had her fast. She could not remove it. She made a good recovery. The fœtus was about two and a half months old.

Society Notes.

AMERICAN ORTHOPEDIC ASSOCIATION.

Third Annual Meeting, held in Boston, Mass., September 17, 18 and 19.

FIRST DAY—MORNING SESSION.

THE Association met in the hall of the building of Natural History, and was called to order at 10.30 A. M., by the President, DR. E. H. BRADFORD, of Boston, who spoke of the recent growth of orthopedic surgery, and of the illustrious efforts and achievements of Sayre, Stromeyer, Langenbeck, Bigelow, and many others.

DR. V. P. GIBNEY, of New York, read a paper on the

TYPHOID SPINE,

in which he first drew attention to a group of symptoms pertaining to the spinal column as sequelæ to this fever, and when pressed for an anatomical diagnosis he used the term *perispondylitis*, meaning an acute inflammation of the periosteum and the fibrous structure which hold the spinal column together. His reason for the use of this term was the production of acute pain on the slightest movement, whether lateral or forward, and the absence of any marked febrile disturbance or neuralgia. He reported three cases. Careful search of text-books failed to reveal any cases of like nature. He then alluded to a similar condition in which the hip was affected.

DR. L. A. WEIGEL, of Rochester, N. Y. (by invitation) read a paper on

THE RELATION OF THE THORACIC AND ABDOMINAL WALLS TO THE SPINAL COLUMN, CONSIDERED WITH REFERENCE TO THE TREATMENT OF ANTERO-POSTERIOR CURVATURE.

He reviewed in a very succinct manner the relation which the thoracic and abdominal walls bear to the spinal column, and endeavored to show that they assist materially in maintaining the upright position of the body, and must therefore be considered in the study of spinal curvatures. He drew the following conclusions:

1. The spinal column in its general upright position is supported by the abdominal viscera, or rather by the resistance of the abdominal walls. Following the force of gravity, the spinal column sinks downward until a resistance is met with. This resistance may be produced either by direct support on the viscera, or indirectly by pressure exerted through the elastic thorax and diaphragm upon the abdominal organs, which are thus forced against the muscular walls until an equilibrium of force is established.

2. By the support which the abdominal viscera give to the spinal column and thorax, the abdominal muscles very materially supplement the action of the erector spinæ muscles by increasing the resistance which the viscera offer to the forward inclination of the spine and thorax.

3. A backward inclination of the spine is limited by the tense abdominal muscles and the firm linea alba to which they are attached.

A contribution entitled

PSOAS CONTRACTION AS A SYMPTOM

was presented by DR. DILLON BROWN, of New York.

He alluded to the various diseases in which this condition may be found, and gave their diagnostic points, emphasizing the phenomena by means of which each disease could be excluded.

DR. A. B. JUDSON, of New York, read a paper on

THE PREVENTION OF THE SHORT LEG OF HIP-DISEASE,

in which he said the deformities of hip-disease are caused by the patient's efforts to so place the limb that it shall be the least disturbed by and afford him the most convenience in his customary attitudes and movements. They are (1) abduction, (2) adduction, and (3) extreme adduction and flexion. The second position is practically by far the most important. It is caused by the patient's elevating that side of the pelvis in order to take the limb off the ground, and to keep the affected limb out of the way of the well one, which is on the ground a longer time than the affected limb, and does most of the work of progression. The limb is maintained in the chosen position by reflex muscular contraction, which does not im-

mobilize the joint, but fixes it in such a manner that changes in its position are readily made by the application of gentle but persistent force. It is proposed therefore to induce the patient—wearing a hip-splint, which protects the joint from the violence of walking—to divide the time on the ground between the two feet, or rather between the foot of the sound side and the ischiatic crutch on the affected side, with the expectation that adduction and flexion will be wholly or in part reduced, when the affected limb makes repeated efforts to reach the ground and does its share in locomotion. It is believed that the patient can be induced by precept and drill to adopt this change in the manner of locomotion, with the result indicated; a belief which is sustained by the observation that patients led by accident to walk in this way have recovered with a good position of the limb, and by the results of the adoption in practice of this method of preventing deformity.

Afternoon Session.

Dr. C. C. Foster, of Cambridge, Mass., read a paper entitled

A CASE OF CARIES OF THE ANKLE TREATED CONSERVATIVELY,

in which he gave a detailed account of the case and its treatment, showing the plaster casts of the foot before and after treatment. He did not claim that all cases should be treated conservatively. He knew that often, especially in hospital practice, resection was the only satisfactory treatment.

Dr. Charles L. Scudder, of Boston (by invitation), read a paper on

REPORT OF CASES OF CARIES OF THE ANKLE TREATED BY EXCISION,

after which patients were exhibited.

He drew the following conclusions: 1. Excision is safe, and the mortality is not great. 2. The convalescence and time of after treatment are short. 3. The disease in the foot is ended; and the prognosis is sure. 4. Profuse suppuration and its consequences are avoided. 5. The likelihood of septic infection is at a minimum. 6. The partial operation of curetting is of very little value. 7. There is no mutilation of the foot. 8. Its usefulness is very great after excision. 9. The question of tubercular infection from operative interference is yet unsettled. 10. Excision of all the diseased bone should be resorted to earlier in the treatment of chronic ankle joint and tarsal disease.

Dr. De F. Willard, of Philadelphia, presented a paper entitled

REST IN THE TREATMENT OF HIP JOINT DISEASE.

He advocates the exploration of the hip with the finger when it has been deemed wise to open an abscess connecting with the joint. The amount of disease could thus be ascertained without injury to the articulation, and dead or tuberculous tissue both of bone and soft parts could be thoroughly removed by knife, scissors or scoop. He advocated a sharp scoop, and especially recommended one which was hollow, thus permitting rapid flushing out of all tuberculous material with sublimate solution before it had time to inoculate the fresh surfaces.

In many cases this removal of tuberculous matter by *incision*, *erasion* and *drainage* was usually sufficient, but in rapid suppurating cases and when a large portion of bone was destroyed, a formal excision through the line of the exploratory incision was often beneficial both as regards life and time.

Ultimate results after either incision or excision are not superior as a rule to those obtained in non-operative cases. Persistence of suppuration and relapses are not uncommon. A partial removal of tuberculous matter might hasten systemic inoculation. Strict antisepsis is necessary.

Mechanical measures that enforce strict and long continued fixation of the joint are of supreme importance both before and after the operation, and no weight must be borne on the limb for at least a year after the sinus has closed.

Primary union was seldom secured and is not especially desired. When erasion is complete the suppurating sac-wall should be excised in toto.

Early excision, while life saving, does not yield as good locomotive results, as are secured by rigid care of the joint.

Free drainage is of the greatest importance.

A paper on

ABSCESSES IN HIP DISEASE, THEIR PREVENTION, SIGNIFICANCE AND TREATMENT,

by Drs. R. W. Lovett and J. E. Goldthwaite, of Boston, was read by the latter.

The treatment of abscesses of hip disease is a question which has been widely discussed, and one upon which diametrically opposed views have been held. No figures bearing upon the relative value of the treatment have yet been brought forward. The large number of cases reported by the essayists were treated at the Boston Children's Hospital. Of 288 cases reported by Dr. Gibney, the mortality per cent. was only 12½. Billroth, following cases after they had left his clinic, found a mortality of 31¾ per cent. Heuter in 86 cases found a mortality of only 27 per cent. In Cazin's series of 80 cases of suppurative hip disease (sent to Berck after they had ceased to improve in the Paris Hospitals), only 12½ per cent. died.

The operation for abscesses in hip disease is not attended with the risk of septicæmia which is sometimes attributed to it, and also that it does not prevent amyloid degeneration from taking place. In 43 cases where the present condition of the patient is accurately known, the abscess wound is closed in 20, and one or more sinuses are still open in 23. Of the cases where the sinuses are still open, in 5 a year has passed since operation, 10 are open at the end of two years, 7 at the end of three years, and 1 at the end of four years. In the 20 cases, 10 sinuses closed within a year after operation, and 6 between one and two years. Finally it may be said that thorough operation is followed in a fair proportion of cases by the speedy closure of the abscesses.

SEPT. 18—SECOND DAY—MORNING SESSION.

This session was devoted to the reading of short papers upon the treatment of hip disease, and papers were read as follows :

The Principles of Treatment, by Dr. N. M. Shaffer, of New York.

The Early Local Treatment, by Dr. A. J. Steele, of St. Louis.

The Operative Treatment, by Dr. De F. Willard, of Philadelphia.

DR. JOHN RIDLON, of New York, reported a case of

CONGENITAL DISLOCATION AT THE HIP.

The patient, a female, aged ten and a half years, came under his observation February 16, 1888. The great trochanter was two and a half inches above Nelaton's line, and it required a blocking under the foot of three inches to make her stand fairly erect. The old pattern of the Taylor extension hip splint was applied, and the leg elevated on an inclined plane. For one year the child did not leave her bed, and no relaxation of the contraction was once permitted ; at the end of this time it was possible to locate the head of the femur, which was found to be displaced upwards and forwards, lying almost directly below the anterior iliac spine, and the difference in the length of the legs was found to be reduced to one-half inch. A jointed splint was applied February 1, 1889, and the patient was allowed up. The case was interesting on account of the direction of the dislocation. He had been unable to find such another case recorded.

DR. BERNARD BARTON, of Buffalo, contributed a paper on

THE IMMEDIATE DISREGARD TO MALPOSITION OF THE THIGH IN THE TREATMENT OF HIP DISEASE,

in which he called attention to a plan of treatment purely fixative in character, which he had employed in the earlier stages of hip joint disease. This plan consists essentially in having the patient suspend himself by the head in the manner required for the application of the plaster-of Paris jacket in spondylitis. During this operation the foot of the well limb is made to rest on a block four to six inches in height, so that the affected limb will, by its own weight, exert traction upon the muscles about the hip joint.

The trunk and limb having been encased in stockinet, should then be wrapped with cotton wadding bandages to protect the surface from the sixth or seventh rib to the middle of the leg ; over this dressing plaster-of-Paris bandages should be applied in a manner to include the trunk, hip and limb within the limits indicated. Then strips of thin malleable steel should be bent to conform to the contour of the body and limb, and inserted between the bandages on the anterior, lateral, and posterior parts of the dressing. As soon as the dressing has become hard, it should be trimmed out on the inner side of the thigh where it passes under the perineum, and all of the edges smoothed to prevent chafing of the skin. A high shoe and crutches having been provided, the patient may be taught their use with the least possible delay. A splint thus formed will hold the hip joint in an immovable manner. It will possess sufficient strength to permit of the patient being lifted or carried without pain or the fear of painful movements of the joints.

In every instance in which the writer had used this dressing the patient had expressed feelings of relief as soon as the splint had been completed.

AFTERNOON SESSION.

The Association met in the lecture-room of the outpatient building of the Children's Hospital.

DR. E. G. BRACKETT, of Boston, read a paper on

AN EXPERIMENTAL STUDY OF DISTRACTION OF THE HIP JOINT.

in which he said the treatment of this subject consists in the consideration of the anatomical possibility of a distraction, influenced by the counteracting forces met in the living subject. The points involved are the resistance by the bony formation, the influence of atmospheric pressure, and the resistance from ligaments and muscles. In the adult the prominent part of the lower portion of the head of the femur rests in the bottom of the acetabulum, which affords a surface nearly horizontal for its support ; and traction is therefore mainly expended in pulling the head down on this surface. When a separation occurs it is shown by a widening at the hips as well as by an elongation of the limb. In children there is no such interlocking of these two bones, but the axis of the joint is more nearly paralled to the line of the leg, and a separation is indicated by an increase in length of the limb, and but slightly by an increase in width between the trochanters. The influence of atmospheric pressure was studied on the cadaver, but the conclusions were that this force was very slight and unimportant, and the effect of traction on the child's joint was studied experimentally on the cadaver, and it was found that there resulted an increase in length of between 2 and 3 mm. in ordinary positions, and 1.5 mm. and less in width.

The conclusions are that anatomically distraction is an evident fact. When clinically considered these results are applicable only with the influence of the muscular force in view. Such would come only from tonicity of contraction. The former is not a working force, but rather a condition of repose. A long continued state of the latter is physiologically impossible, for by our repeated and constant stimulation, the muscles become exhausted, and finally remain in a state of quiet, and in this condition allow as much elongation as would be necessitated by the anatomically possible separation. This behavior of the muscles was demonstrated on a case of congenital dislocation. Two subjects, under treatment for hip disease, who were favorable for an accurate measurement, were examined for any change in this bony relation, and in both a change of 2 mm. was found. The claim was not made for the occurrence of distraction whenever traction was used, nor that it is possible in every case of disease, but it is claimed for a breach of contact of the two surfaces when traction is properly applied under favorable conditions.

MR. JOHN H. HUDDLESTON, of Boston, read a paper entitled

AN ANALYSIS OF TWENTY-ONE CASES OF HIP DISEASE TREATED BY THE THOMAS SPLINT.

He said the splint had been applied in the Boston Children's Hospital by men, some of whom had seen Mr. Thomas' clinics, and others who had carefully studied the directions given by Thomas on the hip, knee and ankle. Special malleable iron for the material of the splint had been obtained, and great pains taken to make the appliance really a Thomas splint. On examining the records of both the hospital and the outpatient department, it was found that since 1881, twenty-one cases of hip-disease had been treated with this splint. No attempt had been made to choose the cases for the splint, but it had been put on in all the stages of the disease, and kept on, in some cases, throughout the course of the affection, and in other cases till the interests of the patient demanded a change. Moreover, it had been used not only as a treatment for the disease, but also as a special remedy for some temporary condition of deformity. Cases were seen once a month or oftener, and were taken from the ordinary class of outpatient cases. Of the twenty-one cases satisfactory notes have been obtained in fourteen, and notes sufficient to explain the use and the result of the splint in five more. One patient died shortly after the application of the splint, and one has not been heard from.

Before summing up the results, it may be added that it has been found difficult to fit the splint and more difficult to keep it in place after fitted. Of the fourteen patients whose histories are long enough to be valuable in estimation of the splint, nine had abscesses; at least nine had elevation of the trochanter above Nelaton's line; eleven had shortening of an inch or more; eight had atrophy of the thigh of more than two inches; five had 5° or more adduction; eight had some flexion; six had no motion at the joint; four had motion of only a few degrees; three had a good amount of motion; one had perfect motion; six were brought into the hospital for correction of deformity or relief of pain.

Finally, the character of the results obtained is shown by the table to be in a broad way: Good position with little flexion and adduction, but great shortening, great atrophy, and very constant elevation of the trochanter above Nelaton's line, with a remarkable percentage of abscesses.

Following the reading of these papers a large number of orthopedic cases were shown, after which the members of the Association visited the hospital wards.

EVENING SESSION.

The Association met at the Tavern Club, No. 4 Boylston Place, at 8.50 P. M.

DR. JOHN RIDLON read a paper on

FIXATION AND TRACTION IN THE TREATMENT OF HIP JOINT DISEASE.

He said the treatment of inflammation in and about the hip joint should, in a general way, be governed by the same principles that govern the treatment of inflammations of like character in other portions of the body, and that physiological rest of the inflamed structures is the chief end to be sought. By *physiological rest* he meant relief from the performance of the normal functions. The functions of the hip joint are motion and the sustaining of weight. Involuntary spasm may give pressure in the same way as does superimposed weight until convalescence is well established, and to counteract the muscular spasm so long as that spasm is in any way harmful. To remove the superincumbent weight, he places the patient in the horizontal position (not necessarily confining him to bed) on a patten with crutches, and a long extension splint. The most effective is obviously the horizontal position; next to this stands the high patten (four to six inches) and crutches, while the most convenient is the long extension splint.

DR. R. H. SAYRE, of New York, read a paper on

EXCISION OF THE HIP JOINT,

in which he said the *first* question that presented itself is whether it is proper to excise this joint under any circumstances, and *second*, if it is a proper operation, at what time is it best done, and in what manner? He believed ordinary cases of hip joint disease to be tubercular; that this tuberculosis is acquired, not inherited; that some additional local influence, such as injury, is necessary to determine the part of the body which is attacked, and that under appropriate mechanical treatment, commenced early in the disease, with good hygienic surroundings, nature, in the vast majority of cases, is able to effect a cure without excision of the joint. Much valuable time had been lost in the past while hesitating to excise. With the present improved methods of wound treatment there undoubtedly was a tendency to operate too early, and sometimes too often. In the operation, pains should be taken to remove all the diseased tissue, provided the patient is not too weak to endure a prolonged operation, and care should be taken to wound as few vessels as possible, and do the least possible damage to surrounding healthy structures, as the chances of general systemic infection are thus much lessened.

SEPT. 19—THIRD DAY—MORNING SESSION.

DR. G. W. RYAN, of Cincinnati, read a paper entitled

WHEN SHALL TREATMENT BE DISPENSED WITH IN SPONDYLITIS?

The writer believed that much might be said on this point. It was a matter which had a wide interest to every orthopedic surgeon, and was never an easy matter to determine. Little was said about it in orthopedic literature, for the reason, probably, that every surgeon believed that each case must be judged individually. He believed also that, as a rule, the orthopedic surgeon kept an apparatus on too long, and that the general surgeon took it off too soon. He had seen many cases of spondylitis in which the appliance had been removed too early, and many others in which he was satisfied that it was kept on too long. He stated that a slight increase in a kyphosis, which was already well-marked, made a very great change in its gait, in the appearance and the growth. The speaker believed that atrophy was, in a measure, a test of the efficiency of the treatment.

The nearer perfect the treatment the greater the atrophy. He believed that when disease was no longer present an appliance was a foreign body, and retarded muscular growth and exercise. No general rule could be laid down concerning the time treatment should be dispensed with, but some indications might be pointed out. Spondylitis might be found in two classes of cases—those who were essentially tuberculous, and those who were not, the disease, of course, being tuberculous in all. He thought that the type of the patient largely influenced the course of the disease. The general health of the patient reflected in a great degree the stage of the disease. Absence of pain was of little value, as efficient support always relieved that. He had often found a compensatory depression beneath the kyphosis indicative of cure, as pointed out by the older surgeons. Time determined little or nothing. Many cases of cervical and lumbar disease got well without treatment, and with fairly good results. Where the surgeon was satisfied that treatment could be done away with, the case must be carefully handled. The matter required a great deal of care, and the appliance should be slowly dispensed with. Massage, cold baths, and faradism were of great service at this time.

Dr. A. J. Steele, of St. Louis, read a paper on

A NEW EXERCISE IN THE TREATMENT OF LATERAL CURVATURE OF THE SPINE.

Afternoon Session.

Dr. W. R. Townsend, of New York, read a paper on

ACUTE ARTHRITIS OF INFARCTS,

in which he said that this was essentially an osteomyelitis in infant life, the difference in pathological conditions being largely due to difference in anatomical conditions and relations of the epiphysis to the joint. Various forms of staphylococci have been found in some cases, notably staphylococcus aureus and albus. The symptoms were quite constant—flexion of joint, the production of abscesses involving the joint, and constitutional symptoms of pyæmia. In the treatment early and complete evacuation of the inflammatory products was necessary, and heart stimulants and tonics should be given. Most cases occurred under one year of age, and in about fifty per centum of cases fatal results occurred. He reported seventeen cases, and from his examination of others found that the joints most affected were the hip, knee, and shoulder.

The following papers were read:

The Treatment by Portative Appliances of Ununited Fracture of the Thigh, by Newton M. Shaffer, of New York.

Operations Upon the Spine for the Relief of Pressure Paralysis, with the Report of a Case, by Drs. Herbert L. Burrell and W. N. Bullard, of Boston.

A Case of Functional Torticollis, Probably Due to Defective Eyesight (with exhibition of the patient), by Dr. R. W. Lovett, of Boston.

A Case of Congenital Absence of Five Ribs, with Resulting Deformities, by Dr. Homer Gage, of Worcester, Mass.

Officers for 1890.—President, Dr. De F. Willard, o Philadelphia; Vice-Presidents, Drs. A. J. Steele, o St. Louis, and A. B. Judson, of New York; Recording Secretary and Treasurer, Dr. G. W. Ryan, o Cincinnati; Corresponding Secretary, Dr. Samuel Ketch, of New York.

On motion, the Association adjourned to meet in Philadelphia, third Tuesday in September, 1890.

Book Reviews.

An Experimental Study of Intestinal Anastomosis with some practical suggestions as to a modified Technique, by A. V. L. Brokaw, M.D., St. Louis, Mo. Reprint from *Weekly Medical Review*, August 17, 1889.

The author's paper is a contribution in a field o surgery which is giving rise to considerable experiment.

It is early to come to any definite conclusions as regards special apparatus. The writer's mode o preparing his approximation rings has the advantage over Senn's plates, in the length of time and trouble required.

The question arises, is there sufficient approximation of tissue to warrant firm and rapid union, which is one of the virtues of Senn's plates? The idea was doubtless suggested by Senn's rubber ring, which is used in implantation.

The clamp, while good, has no advantage over the rubber band.

The operation suggested in gun shot wounds is feasible, but, as the author says, "is of value in some cases." The extent of surface injured, number and location of wounds would govern its application, but where applicable it is preferable to the other forms.

Pamphlets.

The Climate of Southern California in its Relation to Rena Diseases. By P. C. Remondino, M.D., San Diego, Cal President of Board of Health of San Diego, etc. Reprint from *Southern California Practitioner.*

Urinary Calculus and Lithotomy. By Thomas W. Kay, M. D., Scranton, Pa. Reprint from Maryland *Medical Journal*, of March 16, 1889.

Uterine Adeno-sarcoma with Pyometra. By Thomas W. Kay, M.D., Scranton, Pa. Maryland *Medical Journal.*

The Medical Digest.

The most important element in the beginning of the treatment of chlorosis is to relax the bowels. Iron may be administered later.

Three or four grains of chloral hydrate, dissolved in an ounce of glycerine, is recommended as a gargle in quinsy. It is efficient by being locally antiseptic, astringent and sedative.

Sulfonal is recommended for nightsweats by Dr. Boethrick, a dose of 0.5 gms. (grs. vijss) being usually sufficient, and its effect being noticed during the second night in less profuse perspiration.

THE character of the pain will differentiate sufficiently a conjunctivitis from an iritis, says Foucher; in conjunctivitis it is localized in the eye or eyelids; in iritis it radiates round the orbit.

INSTANTANEOUS REMEDY FOR LUMBAGO.—Collodion, tincture of iodine, liquid ammonia, equal parts. To be applied widely over the parts with a camel's hair brush.—*Peoria Medical Monthly.*

USES OF ANTIFEBRIN.—Salhi (*Corresp. f. Schweiz. Aerzte*) found antifebrin to act as a useful palliative in cases of sore throat and diphtheria; also in angina accompanied by high fever, the dose being 0.25 gm. three times daily.

ERYSIPELAS.—

Picric acid	3 parts.
Water	500 parts.

Wash five or six times a day.

—*Calvelli in Revue de Therapeutique.*

ANGINA PECTORIS.—

℞.—Hydrobrom. of cocaine	gr. x.
Alcohol	gtt. xv
Distilled aqua-lauro-cerasi	ʒ vj

Dose.—Inject beneath the skin, during an attack, one quarter or one-half of a Pravaz syringeful.

—*Dujardin-Beaumetz.*

IN blennorrhagia, especially the chronic form, try injections that return, of glycerole with boric acid, of a saturated solution of picric acid, or of the following formula:

℞.—Creasote	gtt. 10
Hamamelis, Hydrastis	āā gtt. 20
Water or water of roses	ad oz. iv.

Dilute the latter solutions so that they will not burn.—BRENNAN, in *L'Union Med. du Canad.*

SUPPOSITORIES FOR ENDOMETRITIS.—Terrier, in the *Revue de Thér. Méd.-Chirurg.*, directs:

℞.—Powdered iodoform	ʒ ijss
Tragacanth	gr. viij
Glycerin, Distilled water	q. s.—M.

For 10 suppositories.

These suppositories should be made in the form of crayons, about the size of a nitrate of silver point, such as is used for cauterizing. Resorcin or salol may be used in place of iodoform in the formula, the same quantity being admissible. If, however, bichloride is preferred, the formula should be altered as follows:

℞—Sublimate of mercury	gr. viij
Powdered chalk	ʒ vjss
Tragacanth	ʒ xxiv
Glycerin, Water	q. s.—M.

For 50 suppositories.

These suppositories should be placed in the cavity of the uterus after the vagina has been thoroughly washed and disinfected with sublimate solution. A tampon of iodoform gauze may be placed in the vagina.

DR. BARRAL has studied the properties of *Illicium parviflorum*, and as a result of his experiments upon dogs, concludes as follows:

Illicium parviflorum contains a toxic principle, causing in dogs vomiting, insensibility, paralysis of the hind limbs and marked tetanic movements.

This plant is poisonous in dosage slightly above 0.50 gr. per kilogr. of the animal's weight. Chemical analysis shows that this substance must be a glucoside, an alkaloid, or a something analogous to the bitter principle. —*La Province Medicale.*

COCAINE IN THE VOMITING OF PREGNANCY.—M. Fraipont Weiss prescribed this remedy in the uncontrollable vomiting of pregnancy, in teaspoonfuls every half hour, of a solution containing 15 centigrammes of the hydrochlorate of cocaine in 150 grammes of water.

Engelmann (of Creuznach), and Holtz used a solution of from three to ten per cent., and ordered it in daily doses of ten to thirty drops. Bois (of Aurillac), tried with equal success, a pomade containing 1 centigramme of the hydrochlorate to 50 grammes of vaseline, and applied this night and morning to the neck of the uterus.

Fraipont himself prefers the hypodermatic method, injecting beneath the skin of the epigastrium an entire Pravaz syringe full of a four per cent. solution. He considers that its administration by the stomach is preferable in cases indicating some quiescent for the nervous irritation of the stomach walls. Such is the uncontrollable vomiting of pregnancy. Bois' method seems to be useful only when the stomach is intolerant of cocaine solutions.—*Ann. de la Soc. Medico-Chirur. de Liege*, August, 1889.

ASTHMA AND THE UTERINE SYSTEM.—Dr. Peyer has recently written in the *Berliner Klinik*, part 9, 1889, on an affection which he terms sexual asthma. He maintained that asthma was always neurotic, and that in different subjects asthmatic convulsions were brought on by the influence of different physical functions. In two young married women coitus caused violent attacks of asthmatic sneezing. In another case the patient suffered from uterine fibroid, with severe asthma, which disappeared after the removal of the tumor. A patient was subject to violent asthmatic fits; on her becoming pregnant for the first time, the asthma was completely cured. In a similar case of asthma, the patient suffered from chronic metritis. When the uterine affection was cured, the asthmatic complication disappeared. In all Dr. Peyer's cases the patients were more or less hysterical, and in two there was a distinct family history of neuroses. The physician must be careful how to distinguish between the possible coincidence of true asthma and disease of the sexual functions and the alleged form where the former is an effect of the latter. In the case of coincidence it is perfectly easy to understand that any aggravation of uterine or ovarian disease and any irritation of the sexual functions might aggravate the asthma. The other condition is less easy to understand, and very hard to prove in a scientific manner.

Is Leprosy Hereditary?—Ortman, in the *Archiv. f. Derm. and Syph.*, Heft iii, 1889, gives a concise abstract of a paper by Dr. Armauer Hansen, in which the author gives the result of an interesting investigation. He went to America to visit the lepers who had emigrated from Norway, and examined in the States of Wisconsin, Minnesota, and Dakota lepers who had originally left Norway, and their descendants born in America. He arrived at the interesting result that of 160 lepers who had emigrated to America, the offspring had remained free to the third generation. This result, the author believes, shows emphatically that leprosy is not a hereditary disease. The fact that, of the 160 emigrants, only 16 or 17 are still alive without any new case having sprung up does not, in his view, show that leprosy is not contagious. He considers that the different mode of life in the new country does not afford the same opportunity of contagion that is given by the peculiar conditions of life in Norway.

—*British Medical Journal.*

Chorea Attributed to Poisoning by Iodoform.—The twenty-fifth annual report of the Jenner Hospital for Children in Berne contains a report of a secondary retropharyngeal abscess in a boy of six years, who was suffering from disease of the cervical vertebræ. Professor R. Demme opened this abscess, and a second, which had reached to the middle of the right clavicle. A little iodoform bougie was introduced in the fistulous canal, and the wound dressed with iodoform powder and gauze. Three days afterwards the boy suffered from headache, and complained of being sick, but the dressing was not changed, and a second iodoform bougie was introduced four days later, when convulsions began to occur gradually, passing on to chorea. The iodoform was then omitted from the dressing, and the chorea disappeared after a fortnight. A few weeks later another practitioner dressed the same case with iodol and iodol gauze, and again chorea appeared, lasting for three weeks.—*London Lancet.*

Pathology of Miners.—In the Section of Medicine of the Congress of Scientific Societies, held at Paris, June 11 to 15, 1889, Dr. Paul Fabre, of Commentry, spoke of the hygiene and diseases of workers in coal mines. His researches treated of (1) anæmia, especially that found among miners; (2) the hygienic condition of the mines; (3) the influence of subterranean work upon health; (4) the elevation of temperature in the mines; (5) the action of moist surroundings upon the workmen; (6) the anoxhæmia of the miners due to the influence of confined air; (7) the effect of the water in the mines upon the health of the laborers; (8) the sanitary condition of miners of the present day; (9) the effect of entozoa, and particularly of ankylostomes; (10) the different causes of the different forms of anæmia among miners.

He classified the diseases to which these men are subject into four groups: (1) of the air-passages (emphysema, chronic bronchitis, bronchial dilatation); (2) of the circulatory apparatus (anæmia, anoxhæmia, cardiac hypertrophy), (3) of the alimentary canal (dyspepsia, gastric vertigo, dysentery, helminthiasis); (4) of the organs of sense (otitis, deafness independent of plugs of wax and coal dust, cutaneous eruptions, such as miliaria, furuncles, erythema, prurigo, conjunctivitis, nystagmus, developed especially among those who work lying upon their backs or in other unnatural positions).—*Le Progrès Médical.*

Antipyrin in the Treatment of Diabetes.—A. Robin sums up the advantages of antipyrin in diabetes, according to his experience, as follows:

It may be employed from the outset in the treatment of diabetes where a glycosuria or acute polyuria is to be reduced without delay.

It is indicated when the diet, long continued and well tolerated, has produced its greatest effect in reducing the glycosuria and polyuria.

A wise combination of diet and antipyrin, associated in a sort of alternating manner, appears to be the best treatment for diabetes.

It is not necessary to continue the use of the drug if it does not produce an immediate and considerable diminution of the glycosuria.

The dose should not exceed twenty grains per diem.

If, with the quantity of urine diminishing, its density tends to increase, the use of antipyrin should be stopped immediately and permanently.

Albuminuria does not constitute an absolute contraindication. Its presence simply involves a question of its dose and of the duration of its use.

Finally, loss of appetite, emaciation, a sensation of weakness, or a sensation of tension in the face, are symptoms demonstrating, where they appear, that the use of the antipyrin is more harmful than useful even if the glycosuria should be influenced favorably.

—*La Semaine Médicale*, 1889, No. 15.

Treatment of Burns of the Eye—A. Trosseau.—Burns *caused by acids* should be treated by a free washing with water, and especially by the use of compresses (placed upon the half-open eye-lids) steeped in an alkaline liquid, as Vichy water. Ice compresses calm the pain, and sometimes prevent the development of inflammation.

Burns *caused by the use of caustics* (potash, lime, etc.), should be treated by very carefully cleaning the cornea and conjunctival cul-de-sacs and washing freely with carbolized water (1 to 200).

Burns *resulting from lime* are particularly serious, as they lead rapidly to perforation and destruction of the cornea, and as they also destroy the conjunctiva and are the cause of consecutive symblepharosis. One may sometimes avoid this accident by neutralizing the base with a very dilute acid, or employing Gosselin's method, which consists of the use of sugar water so as to obtain the soluble saccharate of lime.

We should care for *burns produced by hot metals* (lead for example) by completely cleaning out the eye, carefully removing the metallic particles which may remain fixed in the eye, and then applying over the organ compresses wet with carbolized water.

—*Revue de Therapeutique.*

Medical News and Miscellany.

THE great amphitheatre of the Paris School of Medicine has been destroyed by fire.

THE new training school for nurses opened in Cooper Hospital, Camden, October 11.

PROF. H. EARNEST GOODMAN has returned from his European trip, looking the picture of health.

CAMDEN'S Board of Health has pronounced pigeons kept in cellars as nuisances, but allows hog pens to exist.

DR. C. H. TAYLOR, of the *Medical World*, has just returned from a prolonged tour in France, Switzerland and Italy.

DR. W. B. MADDEN, a prominent physician, was killed at Johnstown, Penna., by an express train, while trying to cross the track near the depot.

A TRAINING school for nurses, in connection with the Johns Hopkins Hospital, Baltimore, was formally opened October 9. It will begin with eighteen students.

DR. HUGH M. SUTHERLAND died in a hospital in New York from the effects of morphine, which he swallowed on Wednesday afternoon in Union Square Park.

REV. SAMUEL JOHNSTON, M. D., an old and well-known physician in the southern part of the city, died on Tuesday at his residence, No. 1816 Christian street.

THE Beaumont Medical College and Hospital, Northwest corner of Walnut and Sixteenth Streets, St. Louis, was destroyed by fire last Tuesday night, October 8.

THE resignation of Dr. T. Gaillard Thomas from the position of Professor of Clinical Gynæcology in the College of Physicians and Surgeons, New York, is announced.

CHOLERA is prevalent at Pekin, and it is said that all foreigners, with the exception of the Custom House officials, and some other functionaries, have fled to the mountains for refuge.

Priceburg, near Scranton, Pa., is suffering from an epidemic of typhoid similar to the famous Plymouth outbreak, and due to water-infection. Fifteen per cent. of the population is said to be affected already.

DR. HIRAM CORSON, of Plymouth Meeting, celebrated his 86th birthday on Tuesday. On that day he read a paper on the "Treatment of the Insane" before the Chester County Medical Society, in Westchester.

AT a meeting of the Reading Medical Association held September 30, Dr. F. W. Frankhauser, graduate of Jefferson Medical College, 1880, Medico-Chirurgical, 1888, was elected president; Dr. Howard Reeves, vice president; Dr. C. Kurtz, secretary; Dr. Raudenbirsh, Dr. Cleaver, censors; Dr. S. L. Kurtz, treasurer.

THE deaths of the following eminent foreign medical men are announced: Dr. Preiss, of Carlsbad; Dr. Oré, Professor of Physiology in Bordeaux; and Dr. Rudolph Voltalini, Professor of Laryngology and Otology in Breslau.

DR. W. H. CORFIELD reported to the Committee of Works of the Parish of St. George that he had failed to trace any connection between the recent outbreak of typhoid fever at the West End, London, and the milk supply.

DR. THOMAS STEWART, SR., a prominent physician of Cumberland county, died at Ontario, Ohio, at the age of 75 years. He was the father of Dr. Thomas Stewart, of Carlisle; Dr. W. J. Stewart, of Newville, and Dr. Sloan Stewart, of Ohio.—*Times.*

A despatch from Ishpeming, Michigan, says that typhoid fever is epidemic in a number of Upper Peninsular towns, notably, at Negaunee and Ironwood, there being nearly one hundred cases in each of these cities. The State Board of Health is making an investigation.

CARBONDALE, Oct. 10.—The State Board of Health has issued a proclamation declaring diphtheria to be epidemic in this city, and Mayor Kelly has issued his edict, calling upon the citizens to place their properties in a healthy condition. There are over sixty cases under treatment.

THE Surgeon-General of the Marine Hospital Service received a telegram recently from Dr. Posey, at Jacksonville, Fla., saying that the president of the State Board of Health reports several cases of yellow fever at Key West. The Surgeon-General says that there is no need of apprehension, and that every precaution has been taken to prevent the spread of the disease.

JOHNSTOWN, Oct. 12.—Fever is raging throughout the city. Many crowded houses have two and three patients in them. All the wards of the Red Cross Hospital are filled with fever sufferers. Money is plentiful, however, and the work of reconstruction is going on rapidly.

TYPHOID fever is epidemic at Aurora, West Virginia, and it is said the country for miles around is infected. "There is scarcely a family without one or more of its members prostrated with the disease, and in some localities there are scarcely enough well persons to nurse the sick."

THE well-known and able ophthalmologist, Prof. Dr. Jacobson, of Königsberg, died on the 16th inst., at Cranz, a watering place on the Baltic. The deceased was the father of Dr. Julius Jacobson, likewise a well-known ophthalmologist, who has been residing in London for several years past.

THE American Academy of Medicine is endeavoring to make as complete a list as possible of the Alumni of Literary Colleges, in the United States and Canada, who have received the degree of M. D. All recipients of both degrees, literary and medical, are requested to forward their names, at once, to Dr. R. J. Dunglison, Secretary, 814 North Sixteenth street, Philadelphia. Pa.

Dr. D. W. Harrington, fifty-five years of age, died in Lockport, New York, yesterday, "evidently from an overdose of morphine." He leaves a wife and son, Rev. P. Harrington, Chaplain of Deveaux College, at Suspension Bridge.

Meeting of the Anglo-American Medical Society.—The first social gathering of the Anglo-American Medical Society took place at the Grand Hôtel, Paris, on the evening of September 30, 1889. This Society owes it origin to the initiative of Dr. Thomas Linn. Among the members who attended were:—Sir Spencer Wells, the distinguished London surgeon, who presided; Dr. Stanley M. Rendall, Aix-les-Bains; Dr. Wakefield, Aix-les-Bains; Dr. G. H. Brandt, Cannes; Dr. F. M. Sandwith, Cairo; Dr. St. Clair Thomson, Florence; Dr. C. E. Cormack, Hyères; Dr. Wm. Niven, Lausanne; Dr. J. A. Barnard, Dr. Boggs, Dr. Bull, Dr. John Chapman, Dr. E. Dupuy, Dr. Faure-Miller, Dr. Hon. Alan Herbert, Dr. Oscar Jennings, Dr. D. Hogg, Dr. Thomas Linn, Dr. C. J. Loughnan, Dr. Nachtel, Dr. J. G. Ponce, Dr. E. Warren-Bey, and Dr. Webb, all of Paris; Dr. W. H. Bagnell, Pau; Dr. F. J. R. Holland, St. Moritz; Dr. Mackenzie, Spa.

Among the invited guests were:—Dr. Madge, of London; Dr. Dean, Dr. Loewenburg, and Dr. Landolt, of Paris; Dr. Worms, of the French Academy of Medicine; Professor Michäelis, of the Paris Dental School; Rev. Mr. Ratcliff, of Paris; Mr. Robert J. Seabury, of New York; Dr. Schetelig, of Hamburg; and Mr. J. H. Hobson, of the Anglo-American Bank.

After the guests had done justice to an excellent *menu*, Sir Spencer Wells rose and proposed the toast of "The Queen, President Harrison, and President Carnot," which was drunk standing. Then "Long Life and Prosperity to the Society" was proposed by the President, and felicitously responded to by Dr. Hon. Alan Herbert. Sir. Spencer's health was given by Dr. Faure-Miller in a neat little speech. Sir Spencer's "heart-felt thanks" were warmly applauded.

Dr. Dupuy spoke to "Our Invited Guests," to which Dr. Worms replied, highly complimenting Sir Spencer Wells on his remarkable achievements in surgery, referring especially to ovariotomy, which the speaker himself, after much opposition from the profession, had at last been able to introduce into France. Dr. Worms then declared that he was sure that English and American medical men would, in the pursuit of their scientific studies, be received in the future, even more than in the past, with that cordiality characteristic of the French medical profession at the capital.

The last toast of the evening was then proposed by Dr. Holland, of St. Moritz, who thanked the Hon. Sec., Dr. Thomas Linn, for having made it possible for them to enjoy such a delightful evening.

Dr. Linn, on rising amidst general applause, said: "In returning thanks for the kind and flattering toast proposed to my health, I can only say that I am pleased to find that my share of the efforts to promote social intercourse and good fellowship between our brethren who practise abroad is appreciated. I trust that the future will increase the present kindly feeling that exists between us, and that we shall *all* meet again next year in good health."

To Contributors and Correspondents.

All articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

The Acutely Ill.

When a patient is acutely ill, the digestive powers share in the general condition, and consequently the food supplied should be of the most easily assimilable character. The predigestion of starchy matters outside the body, as in MELLIN'S FOOD, is necessary, and the soluble carbohydrates of which this food consists, soluble because predigested, form the true food of the acutely ill.—J. MILNER FOTHERGILL, M.D., Edin.

A sample of MELLIN'S FOOD *will be sent to any physician, free of expense, upon application.*

A COMPARATIVE STUDY OF COMMON FORMS OF CONVULSIONS.

(Read before the Chicago Medical Society, October 7, 1889.)

BY ARCHIBALD CHURCH, M.D.,

Professor of Diseases of the Mind and Nervous System in the Chicago Polyclinic.

THE term *convulsion* has been used and is still employed with such widely differing meaning that a definition of the significance it is to bear is a primary consideration. Ordinarily, it is supposed to occupy a median position between tremor on the one hand and spasm on the other; but it often presents both, or shades off into both, yet has features common to neither.

It is desired here by convulsion to designate a more or less extensive, arythmical, *violent*, incoördinate and involuntary activity of striated muscle not controllable by the will, and to predicate of such phenomena a symptomatic position and value.

Convulsions are *clonic* or *tonic*, or both. As ordinarily encountered and here considered, they are associated with epilepsy, chorea, hysteria, tetanus, rabies, strychnine poisoning, uræmia, and acute organic cerebral lesions, embracing hemorrhage, inflammation and trauma.

Under epilepsy it is probably proper to include infantile convulsions, for if not identical in nature, a close relationship exists, as is clearly expressed by the fact that, of epileptics, ten per cent. present convulsions during infancy; and of cases of epilepsy beginning during the first three years of life, two-thirds have so-called infantile convulsions. Widely diverse as are the convulsive phenomena resulting from acute organic lesions of the brain, they yet have a number of common characters which may perhaps justify their being grouped under one head.

Such a classification is necessarily somewhat arbitrary, but is of assistance in discussing the convulsive state. The difficulty inherent to such a subject is made no less by the fact that in the same disease the convulsive manifestations vary within wide limits in different patients, and even in the same patients at different times. By grouping the attending symptoms, however, and selecting fairly typical cases, a tolerably well marked outline can be constructed which will fit upon the observed phenomena in the various diseases and point the way to a diagnosis.

Epilepsy being the convulsive disease *par excellence*, a description of a well-marked convulsion in this malady may serve as a standard of comparison in the examination of analogous displays of hyperkinesis in other diseased states.

The patient, usually in apparently good health physically, but with a personal or family neurotic history, and possibly the record of previous convulsions, presents for a day or two previous to the attack some mental erethism. He is more than usually loquacious or cheerful or boisterous, but more frequently morose, irritable and quarrelsome. There may be vague sensations and a feeling of strangeness, approaching trouble or actual discomfort. At times the facial appearance is changed. It may be puffy or suffused and pale, and rarely a few hours before the fit a dusky hue has been noticed. Finally, with or without an *aura* or warning of any sort, the

convulsion commences suddenly in tonic form. The face is pale, consciousness and sensibility are instantly lost, and the patient falls heavily and lies rigid. The vigorous contraction of the chest muscles, attended by laryngeal spasm at the same time, occasions a peculiar cry—sharp and piercing or guttural and barking. This may be the first intimation of the fit to those about him. A distinct lateral tendency is the rule. The eyes, head and body turn to the right or left, and complete circles may be described before the fall. All the voluntary muscles are affected to some degree, but there is a greater activity unilaterally. At this stage the position assumed is the result of the greater mechanical power of the various groups of muscles implicated. The flexors predominate in the upper extremities, the extensors in the lower. The hands, often clenched, are as frequently in the "inter-osseal position:" that is, the fingers divergent and extended, except at the metacarpo-phalangeal joints. The hand may assume the cone shape of the accoucheur, or, having seized upon an object, may grasp it with wonderful energy. There is a slight tendency to flex the thumb into the palm.

Owing to the contraction of the respiratory muscles and the pressure upon the great vessels of the neck, there occurs asphyxia with cyanosis. The face promptly becomes red, then livid and intensely congested. The lips are a blue-black. The jaws are firmly set, and the tongue or cheek, if caught between the teeth, may be badly lacerated. One can now detect, with the hand upon the tonically contracted muscles, a quivering not noticeable to the eye. This increases, and the clonic stage is developed.

The pupils are dilated, and the open eyes, turned upward and toward the more affected side, present nystagmus or strabismus, or both. The sharp clonic contractions of the respiratory muscles now produce stertorous breathing, and the saliva is forced through the teeth and lips mixed with blood; if the tongue has been bitten, in a bloody froth. The limbs are arythmically contorted in a superlatively incoördinate manner, and all are affected by the clonic spasm; so that the patient is said to be "worked." The urine and fæces may be voided by the action of the abdominal muscles. Gradually the intervals between the clonic contractions lengthen, and the latter finally cease to occur, though the last is usually as vigorous as any, The temperature rises to 102° or 103°. Immediately or following a short period of semi-consciousness, the patient falls into a heavy and sometimes comatose sleep, from which he is aroused after a variable time with headache, muscular pains, and no knowledge of what has occurred during the convulsion, or he may not even appreciate that he has had a seizure. At this time maniacal outbursts are liable to occur. The convulsion lasts from one to five minutes, and is followed after the sleep by a return to full consciousness. Such a convulsion, if seen by a medical man, cannot be mistaken; but in epilepsy the attack may be infinitely modified, and present only one or two of the numerous features which make up the total of a typical seizure. Perhaps the most constant and characteristic indications are the unconsciousness, and following tendency to sleep.

Chorea presents a widely different picture. Only in its severest form are there true convulsions, the ordinary manifestations of hyperkinesis being properly described as spasmodic. In very rare instances the spasms occur with such rapidity that clonic and even tonic convulsions are developed, producing a state which might be confounded with an atypical condition of *status epilepticus* or tetanus, or the epileptoid manifestations of gross cerebral lesions.

The history of the case, the retention of consciousness, the control of the sphincters, the unimpaired cutaneous sensibility, the rapidly-repeated and long-continued spasmodic action, the intervals of complete relaxation, the absence of trismus and pharyngeal spasm are distinctive. Voluntary movements also intensify the spasm and incoördination. A history of acute rheumatism or its coexistence is common, and when present is attended by elevation of temperature with excess of urates and phosphates in the urine.

That multiform disease, which we denominate hysteria, often furnishes imposing and even terrifying convulsive phenomena. They have a proper physiognomy, so to say, though there is nothing in the range of nervous disease manifestations which may not be more or less well simulated in this protean neurosis.

The patient is usually a young woman of an emotional tendency and neurotic inheritance, who has presented from childhood those characteristics which lead a thoughtful observer to entertain fears for nervous stability under unusual strain. Leaving aside the endless other manifestations of the disease, it is desired only to consider its convulsive features when they attain to a degree which calls for their distinction from the hyperkinesis of different origin. As a rule, the convulsion is, so to speak, the climax of an emotional storm. The patient is wrought up to it, or gradually approaches the crisis after a mental strain due to fear, anger or sorrow, but in cases of long standing the convulsions may be brought on with considerable suddenness, and sometimes without the apparent connivance on the part of the one subject to them. In other cases again, there is an aura, something similar to that of epilepsy, which is usually described as a peculiar sensation commencing in the lower extremities or lower portion of the body, and which, gradually creeping upward, overwhelms the patient. A very usual premonition is the *sensation of globus*, which is attributed to a sort of perverse peristaltic spasm of the œsophagus and pharynx. She may fall, and fall heavily, but never mutilates herself, nor disfigures the face, and almost never has an attack when alone. Most frequently a recumbent posture is sought, or the patient quietly collapses and slides to the ground without instantaneous unconsciousness and insensibility, which, indeed, are rarely complete and often not present. There is no initial involuntary scream. If rigidity now occur, it is of a peculiar sort. The lower extremities are extended, adducted, and even crossed; the feet are almost in line with the legs from over-extension, and the toes are curled down in extreme

flexion. The arms are rigidly extended beside the trunk, or at right angles to the body in the so-called "crucial" position. The fingers are firmly clinched upon the inverted thumb, or the thumb is extended between the flexed index and middle fingers. The "interosseal position" is never seen. The head is extended, and a well-marked tendency to *opisthotonos* is commonly present. The eyes are closed, the pupils normal and reacting to light. There may be conjugate deviation or convergent strabismus. Divergent squint is never encountered. Nystagmus not seen. Asphyxia is never prominent, and the breathing is without stertor and the frothing mouth. After a variable time, usually after a number of minutes, clonic movements appear, but they are quite different from those of epilepsy, being symmetrical, rythmical and coördinated. Attempts to control them intensify the muscular action. Often they are merely coarse tremors or twitchings. At this stage theatrical poses, gestures, and emotional expressions with hallucinations and delirium are frequent, and a dramatic element at some period of the outburst is the rule. There may be retention of urine, but loss of sphincteric control of the bladder and rectum is never present. The clonic movements may last from a few moments to several hours, and gradually fade out, unlike epilepsy, in which the last contraction is as strong as the first. Stupor is often assumed. Coma is next to never encountered. The lethargic sleep, so characteristic of epilepsy, does not occur. The pulse and temperature are normal, or only manifest such fluctuations as would naturally attend such mental excitement and muscular effort. The recovery from the convulsion is sometimes prompt, and is often marked by the voiding of a large quantity of limpid urine of low specific gravity. In rare cases, however, anuria of several days duration without uræmic symptoms has been recorded, and in such cases the integument is usually over-active, and may be covered with a fine deposit of urates, the elimination of which is also assisted by the lungs. If the patient does not at once recover her ordinary mental state, a period elapses during which those accustomed to her notice that there is still something wrong, and this state gradually passes away, or is terminated by another convulsion. During the intervals of repose asymmetrical and *bizarre* areas of anæsthesia can be ordinarily determined, and also sensitive zones symmetrically located usually in the ovarian regions, under the mammæ and on either side of the vertebral column. Firm pressure on these so-called hysterogenic zones may determine the premonitory symptoms of a convulsion, or even induce a convulsive attack, and during a convulsion may cause its speedy cessation. Analogous to the cutaneous areas of anæsthesia the visual field is irregularly and asymmetrically contracted, a pathognomonic sign, according to Charcot. There are often local palsies or contractions which may go on to contracture and finally lead to degeneration in the cord. Memory is not impaired, though there may be no recollection of convulsions. Mental application, will power, self-reliance, in a word, psychic equilibrium, is below *par*, a condition at times intensified into positive insanity.

It is to be borne in mind that the male is also subject to hysteria, and may present all its symptoms, even to the tenderness in the position corresponding to the ovarian region in the female, and that hysteria does not preclude other and even organic neuroses.

In tetanus the continuous rigidity is usually marked by convulsive exacerbations, a condition possibly confounded with strychnine poisoning, rabies or hysteria. Three-quarters of all cases of tetanus occur between ten and forty years of age, only one-sixth are females, and traumatism is of record in the large majority of instances. After an incubative period of from ten to fourteen days or less there is usually a period of restlessness and insomnia preceding the development of the muscular symptoms. These invariably first appear in the musculature of mastication and deglutition, and are accompanied or immediately followed by stiffness in the muscles at the back of the neck, but the trismus is the important and characteristic sign. The extension is centrifugally to the face in one direction, to the back, chest and limbs in the other. The upper extremities are rarely affected below the elbows. The distribution of the spasm is symmetrical, with a tendency to opisthotonos from the very first. There is no remission of the contraction, but at intervals, after the extension of the rigidity is considerable, there occur intervals of vigorous convulsive movements which consist of intensified tonic action with the addition of clonic spasm. These exacerbations may be incited by any noise, by an attempt to move, to swallow or to speak, by a slight jarring or even a draught of air. The appearance of the face is characteristic. The lower jaw is firmly fixed by the elevators and depressors usually with the teeth in apposition, but sometimes the dental arcades are not in contact; the corners of the mouth are drawn outward and downward, stretching the thinned lips away from the teeth; the forehead is wrinkled by the corrugators and occipito-frontalis; the staring eyes are partially closed by the orbicular muscles. Various emotions are thus simultaneously indicated; the upper face shows astonishment, the eyes mirth, the mouth anger, and the whole has been denominated the *risus sardonicus*.

There is no strabismus or nystagmus, but the pupils are dilated. The breathing is hindered, and asphyxia follows with facial congestion and cyanosis. Consciousness may be lost momentarily. Guttural sounds are occasionally produced by the spasmodic action of the respiratory muscles, and implication of the diaphragm gives rise to a characteristic ventral pain. Sometimes the tongue is caught between the teeth and lacerated. These exacerbations last from five to twenty seconds, are extremely painful and much dreaded by the patient; who is conscious through it all, and until the last, except at brief moments, when the asphyxia is intense. If sleep is obtained there is only partial relaxation. The continued spasm of the sphincters determines constipation, and retention of urine which is of high color and specific gravity, though presenting no increase of nitrogenous material even during hyperpyrexia. The temperature is fickle and depends largely on the nervous element. Often there is no elevation of bodily

heat, but again it runs up to 102°–103° and even 107°, associated, as was pointed out by Verneuil, with the intensity and frequency of the convulsive attacks. The pulse is small and thready, pointing to vaso-motor spasm. The deep reflexes are at first subnormal or unchanged, but later are exaggerated; as is the cutaneous sensibility. Death results from asphyxia, exhaustion or hyperpyrexia. In the small percentage of cases going on to recovery (15 per cent.) the convulsions grow more rare and less violent, the rigidity less intense, muscular weakness and even paralysis often persist, but relapses are unknown.

In rabies, as in tetanus, the greater proportion ($\frac{5}{6}$) of patients are of the male sex, owing undoubtedly to their greater exposure to the bites of rabid animals. The convulsive phenomena in this disease are developed only in the later stages. There is first of all a history of the bite by a representative of the feline or canine family supposedly or actually rabid. The incubation period lasts from one to nine months; during which the health may have been unimpaired. Restlessness, malaise, insomnia, some pain in the region of the bite, are prodromal symptoms, followed in a few days by pharyngeal and laryngeal spasm, producing precordial pain, difficulty in swallowing, and a sighing respiration marked by catching of the breath as if the patient had been suddenly subjected to a drenching with cold water.

The breathing is labored, of the upper chest variety, and carried on by the superior extraordinary muscles of respiration. There is shivering and sometimes an intensification of this which may properly be designated as a general clonic convulsion. The pharyngeal spasm increases, the horror of water becomes intense, and any attempt to drink, or the sight of water, or sometimes its mere suggestion, determines convulsive contractions of the muscles of deglutition and respiration in which those of the face may participate. Meanwhile thirst is constant and the patient exerts himself to overcome the convulsive inability to satisfy it, but without avail. Cutaneous and special sensibility become enormously exaggerated. The slightest touch or breath of air may renew the convulsion. Sounds inaudible to the attendants are plainly distinguished by the patient. Magendie reports the case of a child born deaf and dumb that heard during the later phases of hydrophobia. The pulse is irregular and thready. There is constant insomnia. Hallucinations of hearing and sight are common, and delirium at times appears, in which the patient attacks those about him, sometimes tries to bite them, at others to escape and roam at large, or secrete himself. The inability to swallow the saliva, and the addition thereto of bronchial mucus, determines a constant flow of thick glairy fluid from the mouth, which distresses the patient and causes constant efforts at expectoration. Vomiting of dark brown material is common. The convulsions become more frequent and more extensive. They are now marked by tetanoid rigidity with opisthotonos, but present complete, or nearly complete, remissions, and trismus is absent or only appears at a late stage. Priapism and ejaculations are frequently recorded. The convulsive movements are manifestly coördinate and often hysteroid in character, lasting but a few moments at each access. Aside from photophobia the eyes are not characteristically affected. Sometimes the tongue presents on the lateral borders a number of vesicles to which the ancients attributed much importance and which gave the name "lyssa" to the disease. The voice is changed, being hoarse and accompanied by a rasping cough which has fancifully been likened to the barking of a dog. The urine is frequently albuminous and sometimes presents sugar. The temperature ascends *pari passu* with the increase of the convulsions and may reach 104-5° or 106°. The asphyxia becomes more marked at each access, and finally, as a rule, is the cause of death, but the fatal termination may depend on heart failure or a generalized paralytic state similar to that which terminates most generally the disease in the lower animals. The result is invariably in death in from one to four days. The distinctive signs are pharyngeal spasm, sighing or "catching" respiration, inability to swallow, dread of water, clonic convulsions, preceding the tonic, intense cutaneous sensibility, and the thick salivary discharge from the mouth.

Serious poisoning from strychnine, fortunately, is very rarely encountered, but its medico-legal importance requires familiarity with the convulsive indications of its action which have at times been confounded with similar conditions of other origin. The symptoms are much modified by a variety of circumstances, such as the presence or absence of food in the stomach, or the existence of any disease which retards assimilation. The quantity of the drug determines proportionate results. The method of its exhibition, whether hypodermically or otherwise, also influences the rapidity of its operation. Ordinarily, in a few minutes after the ingestion of some alimentary or other substance which may have had a bitter taste, symptoms of excitation of the nervous system are developed. If the dose is comparatively small there is mental excitement, overactivity of the special senses, restlessness, itching of the skin, and a subjective greenish hue before the eyes. Then occurs muscular twitching, most marked in the face and extremities, followed by tetanic general convulsions. If the dose has been large the convulsions are of immediate occurrence. They resemble in action, distribution, and intensity the exacerbations of tetanus which have been above described, but last only from one-half minute to three minutes, and are followed by complete relaxation. They rarely present trismus, and that in only the later stages.

As a rule, there are but four or five convulsions in fatal cases, occurring at intervals of from five to fifteen minutes. They may be incited by an unexpected noise, a jar, or a draught of air; but when the patient is forewarned of such excitants, no convulsive effect is produced—a distinguishing feature from the hyper-excitability of tetanus and rabies, in which volition seems to be powerless to control the discharges of nerve force. In non-lethal cases, the convulsions grow less severe and the intervals longer.

DIFFERENTIAL TABLE.

Convulsions in.....	EPILEPSY.	SEVEREST FORM OF CHOREA.	HYSTERIA.	TETANUS.	RABIES.	STRYCHNINE.	URÆMIA.	ACUTE CEREBRAL ORGANIC LESIONS.
Age.....	3-4 of all cases begin under 20 years.	9-10 of all cases occur from 5 to 20 years.	9-10 of all cases are under 30 years.	3-4 of all cases occur from 10 to 40 years.	Any age.	Any age.	Usually adults.	Usually adults.
Sex.....	5 males to 6 females.	1 male to 3 females.	1 male to 20 females.	6 males to 1 female.	5 males to 1 female.	Either sex.	Either sex.	Either sex.
Present History....	Of previous attacks and heredity.	Of rheumatism chorea and heredity.	Of previous attacks and heredity.	Of traumatism in 3-4 of all cases.	Of bite of rabid animal.	Of ingestion of some substance.	Of disease giving rise to blood infection.	Of traum. apoplex., fever, etc.
Prodromata.....	Changed appearance, mental erethism an aura.	Changed disposition, forgetfulness, choreic movements.	Emotional excitement.	Mental erethism.	Excitement, insomnia, changed disposition, pain in wound.	Anxiety, exaggerated sensibility, special and general Green hue before the eyes.	Irritability, neuralgias blindness.	Hebetude, coma.
Onset.....	Suddenly with peculiar cry. Tonic.	Gradual intensification of choreic movements.	Rarely suddenly, usually after other hysterical manifestations.	Trismus always initial, and tonic spasm prominent.	Pharyngeal spasm, catching respiration, shivering and clonic manifestations.	Twitching of face and extremities, clonic followed by tonic convulsions.	Usually sudden in tonic form.	Often sudden and clonic.
Muscular Distribution in Order of Implication.....	All voluntary and some involuntary muscles at once.	Face and extremities becoming generalized.	All voluntary muscles in no particular order.	Muscles of mastication deglutition, back of neck, respiration, trunk, arms and lower extremities.	Muscles of pharynx, larynx, respiration, trunk, limbs, face.	Muscles of face and extremities becoming generalized.	General as in epilepsy.	Localized, one extremity or one side of body, etc.
Coördination.....	Totally lost.	Lost.	Not Lost.	Lost.	Partial, becoming lost.	Lost.	Lost.	Lost.
Symmetry of Movements.....	A lateral tendency well marked.	Lost completely.	Well marked.	Both sides act together.	Both sides act together.	May be symmetrical, but usually not.	As in epilepsy.	No symmetry.
Sphincters.....	Control lost.	Control retained.	Control completely retained.	Spasm causing retention.	Control rarely impaired.	Control retained, tendency to spasmodic retention.	Control often lost.	Control may be lost.
Eyes.....	Open, pupils dilated, not reacting, strabismus, nystagmus, winking, conjug., deviation.	Blepharospasm, nystagmus.	Closed pupils, normal and reacting to light; may be closed. Strabismus.	Partially closed by orbicular spasm. Pupils dilated.	Usually unaffected.	Strabismus—orbicular spasms.	As in epilepsy.	No symmetry.
Mouth.....	Frothing.	Sometimes frothing.	Never frothing.	Teeth uncovered, lips thin and retracted.	Flow of thick, glairy saliva, etc.	Not frothing.	As in epilepsy with flapping cheeks and frothing mouth during coma.	As in uræmia.
Tongue.....	Often bitten.	Rarely bitten.	Never bitten.	May be bitten.	Very rarely bitten.	Not often bitten.	Rarely bitten.	Rarely bitten, may deviate, etc
Pulse.....	Tense and rapid.	Rapid and variable.	May be normal.	Indicates vaso-motor spasm.	Weak and thready.	Irritable, variable, rapid and unequal.	Indicates vaso-motor spasm.	Often full and tense, varies according to seat of lesion.
Temperature.....	Elevated 103°.	Elevated during convulsions and rheumatic conditions.	Normal.	Often reaches 106°.	106° in terminal stages.	Elevated in tetanic stages.	Often subnormal.	Variable, may be elevated or depressed.
Urine.....	Normal.	Excess of urates and phosphates in rheumatic conditions.	Large quantity and limpid.	Retained; high color, and sp. gr. No excess of nitrogenous material.	May present albumen or sugar.	Normal.	Albumen and excess of nitrogenous material. May be suppressed. Usually small in quantity.	May be retained or overflow. Often ammoniacal.
Asphyxia.....	Prominent in tonic stage.	Absent.	Absent.	Prominent feature of the exacerbation.	Occurs in tetanoid stage.	Occurs in terminal tetanoid attacks.	Not prominent.	Often present in moderate degree.
Coma.....	Rarely follows convulsions	Absent.	Absent.	Absent.	Absent.	Absent.	Prominent and continuous.	Often prominent and continuous.
Consciousness.....	Promptly lost.	Not lost.	Only partially lost.	Lost during severe asphyxia.	Lost during severe asphyxia.	Lost during severe asphyxia.	Lost during convulsions and coma	Lost during coma and severe convulsions.
Cutaneous and Special Sensation.....	Lost during convulsion.	Not lost.	Not entirely lost; often presents areas of anæsthesia, sensitive zones, and limitation of visual field.	Exaggerated.	Much exaggerated.	Very much exaggerated.	Subnormal. Lost during convulsions and coma.	Often presents areas of anæsthesia and defects of special senses.
Duration of Convulsion.....	1 to 5 minutes.	Continuous for hours.	A few minutes to several hours.	5 to 30 seconds.	5 to 30 seconds.	5 to 30 seconds.	1 to 5 minutes.	1 to 5 minutes.
Paralysis.....	None.	Very rare—often weakness.	Frequent.	Sometimes a sequel.	None.	None.	None.	Frequent and limited.
Pain.....	Muscular pains and headaches follow convulsions.	Rheumatic pains.	Neuralgic pains.	Ventral pain and severe pain in contracted muscles.	Precordial pain and painful cramps.	General shooting pains worst during convulsions.	Various.	Headaches and localized pains.
Usual Termination of Disease.....	By intercurrent affection—rarely in status.	In this form often fatal from exhaustion.	Never fatal.	Usually fatal from exhaustion or asphyxia.	Always fatal from Asphyxia, exhaustion or generalized paralysis.	Depends on dose. Fatal cases end in asphyxia or exhaustion.	Often fatal from exhaustion or cardiac failure.	Often fatal from exhaustion, heart failure pulmonary œdema.

In fatal cases, death occurs from asphyxia during the tetanic rigidity, or from exhaustion. The entire course of the poisoning is comprised within the limits of four or five hours. Its abrupt onset, the rapidity of its course, the lack of initial trismus or pharyngeal spasm, the mental clearness, the intervals of complete relaxation, make up in this convulsive state a picture which can scarcely be mistaken.

Uræmia, dependent upon Bright's disease, the puerperal state, scarlatina, and other of the febrile infectious maladies, is often marked by convulsions which strikingly resemble those of epilepsy and the epileptic status. When the disease which gives rise to the uræmic condition is recognized, the character of the attack is, of course, manifest. As a rule, the onset is comparatively sudden and unexpected. It may, however, be preceded by twitchings, irritability, loss of sight, neuralgia of the fifth nerve, tingling, formication, and mental distress. In the parturient woman, there is often an interval of quiet and drowsiness before the attack. Various degrees of severity are encountered, from a slight clonic movement in a few groups of muscles or in one extremity, to the most pronounced and frightful convulsive manifestations imaginable. The type presents a sudden tonic convulsion, followed by clonic movements, with all the characters of a true epileptic seizure excepting the initial cry. A distinctive point is that coma follows and persists until the next convulsion, which occurs after a variable interval—sometimes after several hours. The persistence of coma is also true of the epileptic status, but the convulsions in epilepsy occur with much greater rapidity.

The circle of phenomena is described with a shorter radius, so to speak, and fifty or an hundred convulsions in a day are not uncommon, while in uræmia four or five would be nearer the average for that length of time. Moreover, status is always a late stage of epilepsy, the history of which, when obtainable, should prevent error. In uræmia, also, the temperature is ordinarily distinctly subnormal, unless active febrile movement is determined by the attending disease. Œdema, pallor, waxiness, or the history of fever directs attention to the urine. The presence of albumen, or a condition of anuria, constitutes a strong indication of the uræmic etiology of the convulsions.

In acute organic cerebral lesions, the history previous to the convulsions is of the utmost importance in their diagnosis. The temperature and characteristic headaches of meningitis, the possibility of the extension of meningitic trouble, from depots of purulent infection, as in the ear, the sudden onset of hemorrhage, and the evidence or history of traumatism, all have weighty significance. The convulsions have the common feature of being caused by a more or less localized, persistent, and irritating condition, which gives rise to repeated discharges of nerve force. They present, ordinarily, a superabundance of clonic movements, and the tonic element may even be entirely lacking. As a rule, the convulsions are not generalized, but are often so distinctly limited to a limb or a group of muscles that the brain lesion can be definitely localized. Areas of anæsthesia and hyperæsthesia and limited palsies point in the same direction, especially when anatomically associated. There is a well-marked tendency to continuous somnolence and coma. The temperature is fickle, depending on the cerebral implication, which also gives rise to a variable pulse. There may be incontinence of urine and fæces, or retention of urine with overflow. A tendency to bed sore is common. Strabismus, inequality of the pupils, optic neuritis, and paralysis of cranial nerves are not infrequent. Vomiting, of an inveterate expulsive sort, of apparent cerebral origin, is common, The convulsions may present all degrees of severity, but the mode of onset in a particular region, or other focal symptoms, usually make the character of the fit sufficiently manifest.

Appended is a tabular arrangement in parallel columns of these various forms of convulsions, with their symptoms and characters briefly indicated under twenty-three heads. (See page 605.)

ANTIPYRETICS, ANALGESICS AND HYPNOTICS.

(Read to the Missisippi Valley Medical Association at the Fifteenth Annual Session, September 10, 1889.)

By I. N. LOVE, M.D.,

President Section on Diseases of Children, A. M. A., Professor Diseases of Children, College Physicians and Surgeons, St. Louis.

IN this short paper I shall not attempt to treat of my subject, or rather trio of subjects, exhaustively or analytically, but only in a general way.

It goes without saying that antipyretics are remedies which reduce the body temperature when it is above the normal point.

We have had for many years a long list of remedies which properly come under this head, all accomplishing the same end more or less actively, but in different ways.

Some act by lessening the tissue changes, such as quinine; some by reducing the circulation, as digitalis, aconite, leeching, cupping or bleeding; others, like alcohol, by dilating the vessels of the skin and producing increased radiation; others, again, by stimulation of the sweat glands, and the evaporation following, such as Dover's powder and antipyrin; last of all, those which abstract heat from the body, cold baths, cold drinks, wet-packs, etc.

Quinine has for a long time taken high rank as an antipyretic, but the profession has now arrived at the point, I believe, where other means are to be preferred, save in high temperature due to inflammation and to septic causes.

I think it should never be given to reduce the temperature in typhoid fevers; the demoralizing effect upon the stomach and nervous system is greatly to be feared. In these conditions, the cooling bath, coupled with antipyrin, acetanilid, and the new drug belonging to the same class, exalgine, to which I shall refer more fully later, are, I think, much more desirable. They have the advantage of not only reducing the temperature, but at the same time calming the nerve centers, and the last three of rendering the alimentary canal antiseptic.

En passant, I would like to emphasize the point that whatever the means used, the reduction should

not be made too suddenly and in excess. A gradual reduction is safer and more readily maintained.

Of all analgesics or remedies which relieve pain, opium and its derivatives stand first on the list, but there are many conditions where so powerful a remedy, or one so disposed to check the activity of the secretory glands, is contraindicated. Such cases are accommodated admirably by the modern coal tar products previously referred to, viz.: antipyrin and acetanilid.

I am already on record as favoring the latter drug, on account of its being more active, safe, reliable and reasonable in price; and, besides, it is not as potent a medicine as is antipyrin. This preference is based upon nearly two years' study and comparison of recorded bedside observation.

Sleep producing agents in the fullest acceptation of the term would naturally include all or many of the drugs which reduce temperature or allay pain.

The bromides, of course, are the most popular and purest hypnotics we possess, but chloral hydrate is one which deservedly ranks high.

Urethan, a new, or comparatively recent hypnotic, I have found of considerable value, and it possesses a great advantage over the two previously mentioned in that being very soluble in water, and non irritant to the tissues, it can readily be given hypodermically.

When given in sufficient quantities, ten to twenty grains, if a reliable product be used, it can be depended upon, unless the element of pain enter into the case as a cause of the restlessness, in which case it will fail.

Prof. Coze, of Nancy, has demonstrated urethan to be an absolute antagonist to strychnine. Potter's Hand-Book suggests that this fact would indicate that urethan would be useful in any form of convulsions, and especially in tetanus.

Exalgine, which has recently been added to the class represented by antipyrin and acetanilid, through the labors of Brigonnet, of the Cochin Hospital, has now been before the profession for some months.

A favorable pronouncement regarding this drug by Dujardin-Beaumetz prompted me to secure a goodly supply, and use when indicated. Two months' systematic use of the drug, while not absolutely convincing to me, has so favorably disposed me to it as to justify a continued and more enlarged application of it.[1]

Messrs. McKesson & Robbins furnish a two and a half grain gelatine coated pill of exalgine, which is a convenient means of administration. I have generally given one or two of these pills, according to age or conditions.

It has been claimed that this drug does not produce cyanosis, as do antipyrin and acetanilid. In a few cases I have observed slight cyanosis. However, I do not believe that this symptom, even when produced, is important.

I have administered exalgine in typhoid fever to good advantage. It reduced the temperature gradually and without depression, and aided in the securement of rest.

Owing to the impaired digestion in these cases, I have almost uniformly given the following formula:

℞.—Exalgine (McK. & R.)	℈ ij
Sp. vini Gallici	ʒ j
Elix. lactopeptine	ʒ iij

M. Dessertspoonful every two to four hours, as indicated.

An elegant and agreeable form to give the drug is the Exalginique Cordial, prepared by McKesson & Robbins. Each tablespoonful contains two and a half grains of exalgine, but the cordial will take up as much more exalgine very readily, if one desires to increase the strength. For delicate and æsthetic patients this is an admirable means of administration.

I agree with many observers that the analgesic property of exalgine is the predominating one.

I have observed no marked depression from the drug. The skin is rendered more active, and I think the secretions of the alimentary canal are favorably affected. The urine is somewhat diminished, and in a case of diabetes the amount of sugar was decreased. Rheumatism and neuralgia were favorably influenced.

A case of facial neuralgia in a physician was very satisfactorily treated by the use of exalgine. The paroxysms were relieved when present, and were prevented by doses of exalgine in anticipation.

If the medical profession had never accomplished more for human kind than that which it has done in the direction of relieving pain and securing sleep, no one could say that its mission had been in vain.

Pain, while being of great aid to us in diagnosis, is, if left unrelieved, a cause of exhaustion of nervous force, a destroyer of sleep, appetite and digestion. If long continued, it leads to changes shortening existence. It may in itself be so severe as to abruptly terminate life.

I believe it is the duty of the physician to save his patient any possible twinge of pain, within proper limits, of course; but in doing so he should guard carefully against the possibility of self-drugging upon the part of the patient. With this end in view, I deem it to be the physician's duty for him to dispense directly to patients all analgesics and sedatives. By so doing he limits absolutely the amount taken, at least it cannot be long continued against his orders. Another advantage is that, when desirable, and that will be in nearly all cases, he can keep from his patient a knowledge of the drug taken.

I think we are safe in concluding that all of the derivatives of the aromatic series, being antiseptic, antipyretic, and analgesic, are of great value to us in our battles with disease.

Acetanilid so far stands at the head of the list in my records, for the reason that I have had a longer and more extended experience with it.

The brief experience I have had with exalgine has been so satisfactory as to justify a more extended use.

We have received several queries about a note in our issue of August 10, concerning the use of biniodide of ammonium for removing powder stains. It seems that our druggists are not aware that such a salt exists. The note was from the *Revue de Thérapeutique Medico-Chirurgicale* of June 15, and is a correct translation.

THE KEMMLER CASE.

By T. D. CROTHERS, M.D.,
Superintendent Walnut Lodge, Hartford, Conn.

WILLIAM KEMMLER was tried and convicted of murder at Buffalo, New York, May 10, 1889. He was sentenced to be executed by electricity under the new law. An appeal was taken on the ground that the law abolishing hanging and substituting electricity was wrong and unconstitutional, etc. A stay of sentence was granted, and a referee appointed to take evidence concerning the methods of carrying out the death sentence by electricity. A great amount of most valuable testimony has been taken; some of it confusing and contradictory, from the leading electrical experts of the country. The question to be determined was the certainty and painlessness of death from a current of electricity, and certain legal questions as to the meaning of the law from its wording.

These questions have made the case a celebrated one, and will form the basis of a new literature, involving new points of law and science. Unfortunately for the credit of the common legal practice, this test case is that of an alcoholic and idiotic dement, the trial and condemnation of which brings out in lurid colors the injustice of the law, and the forcible application of mediæval theories of mind and human conduct.

William Kemmler, about twenty four years of age, a huckster, came from Philadelphia, Pa., where he was born, to Buffalo, in 1888, deserting his own wife, and bringing with him another man's wife as his paramour. They frequently quarreled, and the woman had threatened to kill him if he did not stop drinking. He had drank to intoxication every night for a long time before the commission of the crime. One morning he got up, went to the barn and gave some order about the care of his horses, then went to the house, and after a quarrel, struck this woman with a hatchet, inflicting twenty-six wounds, from which she died in a few hours. He told a lady who came to the door that he had killed his wife and would take the consequences. He went with another man for a doctor, and drank on the way, and finally gave himself up in a saloon soon after. He appeared dazed and silent after the commission of the crime for some time. He was given two dollars' worth of spirits at the station, and made several contradictory statements. Was examined by physicians and pronounced sane, only suffering from excessive use of spirits. The murder was committed the 29th of March. He was indicted and put on trial May 6 for murder. The testimony was a most startling history of excessive use of spirits by both the prisoner and his friends. It appeared that he had drank from twenty to thirty times a day, and often on a wager to show his power of out-drinking other men. He had been successful as a trader, but generally drank every night, and sometimes was very stupid. His father drank to excess at times all his life, and his mother died of some form of insanity in his infancy. He was brought up on the street, and began to drink beer at ten years of age. Had syphilis early in life and frequent attacks of it up to the time of the murder. He was of small stature, low browed, small, irregular brain, eyes sunken and unsteady, with a stealthy, suspicious look.

He has a hesitating, idiotic way of talking in a whining undertone, and is clearly dull of comprehension. He has always lived in the lowest surroundings, and has a defective brain development. His two brothers clearly resemble him in defective, irregular shaped heads and body. The prisoner had delirium tremens, or alcoholic delirium, several times. His father also suffered from this at different times in his life. Such were some of the facts which appeared on the trial.

The prisoner plead guilty to murder in the second degree, and the defense was that a man in this condition could not be responsible, and hence should not be punished to the full extent of the law. As an expert I testified that the prisoner was an alcoholic dement, and irresponsible maniac, basing my conclusions on the following facts:

1. He inherited an alcoholic diathesis and predisposition to use spirits from the slightest provocation. His inebriate father and insane mother entailed upon him brain defects from which he could not escape.

2. His early life of neglect, and early use of beer, poor, irregular food, no training, bad hygienic surroundings, all favored the growth of alcoholic excesses.

3. The frequent attacks from syphilis, and the excessive use of alcohol—which, during the last two years, had increased greatly—were all conditions which would break up the normal sanity of any one, particularly if he inherited mental defects from his parents.

4. The cool, insane-like character of the murder—killing his paramour with a hatchet, striking twenty-six blows in different parts of the body and head, when a saner mind would have struck but one blow—then giving himself up, with no effort to escape or deny the crime.

5. He had been intoxicated the night before the crime, and had for a long time been jealous of this woman. The morning of the crime he appeared dazed, like one who had not recovered from the effects of the alcoholic excess the night before; talked about the crime; then later denied all memory of it. He had been drinking continuously for the year and more that he was in Buffalo, and also a much longer time before he came to Buffalo to live.

6. His conduct in the jail and during the trial showed no clear comprehension of his crime or its consequences. His idiotic appearance, together with the history, confirmed all the above conclusions.

Many other facts fully sustained this theory, and there seemed not a link wanting in the chain of causes and conditions pointing to alcoholic dementia.

The State assumed that, as he had conducted his business of a street peddler of vegetables with fair success, and showed some good reason in buying, and was not considered by his associates as anything more than a hard drinker, who sometimes did very unusual things when intoxicated, he must be sane and responsible for the crime. The heredity was ignored, and the crime was only considered as brutal

and vicious, and not lacking in any way the ordinary comprehension of a sane man. Two physicians thought that there was no evidence of any form and degree of insanity, and no appearance of idiocy or dementia in his manner. They swore that the use of alcohol to excess did not necessarily impair the brain or destroy the consciousness of right and wrong. The demented appearance of the prisoner was thought to be simulation of insanity. The judge, as usual on such occasions, charged the jury, leaving a most confused notion of law, fact and practice, and asking them to determine the value of the evidence and decide the most difficult questions of responsibility and mental health. The verdict was guilty of murder in the first degree. The facts of the prisoner's life, conduct and present state were ignored as of no value. The press echoed the sentiment of the court and demanded that Kemmler should hang. The defence of limited responsibility and lessened punishment was called subversion of justice. Some of the facts of unusual interest in this case are:

1. The failure of the court or medical witnesses to recognize the incapacity of the prisoner, and brain unsoundness and incapacity to realize the nature of his acts or their consequences.

2. To assume a state of sanity from the absence of hallucinations, delusions or mania, and judge the case from some narrow, imperfect study of the facts of the crime was an inexcusable blunder.

3. The assumption, that a defective-brain man could use alcohol to excess from early life, have syphilis and live badly, act strangely, and yet be fully responsible, is to ignore every advance of scientific study.

The zeal and haste of the State to convict such a case of murder in the first degree, is a sad reflection on common justice and humanity.

Such a case should have been sent to prison for life, for the reason that no other place is open to receive him. Law and technical psychology would differ about his mental condition, and shut him out from the insane asylum. This case has become celebrated as to how the death penalty shall be inflicted. Whatever the result may be, the trial and verdict of the jury were a disgrace to the intelligence and common sense of our present civilization.

This, like many other cases, shows the need of a larger, more accurate, scientific study before we can approach to any degree of justice in the treatment of criminal inebriates.

The following statements of conclusions which experience and scientific study are daily confirming, may be of interest:

1. The legal treatment of insanity has changed in obedience to a more accurate knowledge of the brain and its diseases.

2. The legal treatment of inebriety is unchanged to-day. Although it occupies two-thirds of the time of courts, all teachings of science and a larger knowledge of the inebriate and his malady are ignored.

3. The ruinous error of punishment of inebriety, and petty crimes associated with it, by fines and imprisonment, which notoriously increase and perpetuate the inebriate and criminal, is a fact demonstrable in every community.

4. Thus public opinion, through mediæval theories and laws, is training and preparing a class of inebriates who first commit petty, then capital crime, with a certainty which can almost be predicted.

5. The death penalty for such crime utterly fails for the same reason. The execution of any number of this class simply opens the door for an army already prepared and trained to take their places.

6. From a scientific study of these cases, it is clearly apparent that they are diseased and incapacitated to act sanely. Alcohol has palsied the brain and made them madmen. The very fact of continuous use of alcohol is evidence of mental impairment and unreasoning act and thought.

7. To hold such men accountable for their acts, and by punishment expect to deter them from further crime, and by such punishment check others from similar crime, is an error which both scientific teaching and experience point out.

8. The object of the State, through the law, is to protect society and the individual; but if the execution of the law-breaker fails to accomplish this end, the laws are wrong.

9. The unfounded fear that the plea of insanity in crime, and the failure to punish, is an encouragement for further crime, is flatly contradicted by statistics.

10. Among the mentally defective—the insane and inebriates, the death rate is followed by an increase rather than a diminution of crime.

11. The inebriate should never be hung for crime committed while under the influence of alcohol.

12. The method of punishment is never deterrent, but furnishes an attraction for other inebriates, who commit similar crime in the same way, following some law of mental contagion.

13. The inebriate murderer should be confined the rest of his life in a military work-house hospital. He should be under the care of others, as incapacitated to enjoy liberty and incompetent to direct his thoughts or acts.

14. A change of public sentiment and law is demanded, and a readjustment of theory and practice called for. The criminal inebriate occupies a very large space among the armies of the defective who threaten society to-day, and his care and treatment must be based on accurate knowledge, not theory.

15. Inebriate murderers should never be placed on public trial, where the details of the crime are made prominent, or the farcical questions of sanity are publicly tested. They should be made the subject of private inquiry, and placed quietly in a work-house hospital, buried away from all knowledge or observation of the world.

16. The contagion of the crime and punishment would be avoided, and his services might repair some of the losses to society and the world.

For the removal of tape-worm the *Northwestern Lancet* advises eight grains of salicylic acid every hour until five or six doses have been taken; then give a good big dose of castor oil. It is said to be very effective.

Hydrotherapeutics.

Attending Physician New York Juvenile Asylum and Manhattan General Hospital.

VII.

CONTRA-INDICATIONS TO COLD BATH TREATMENT OF TYPHOID FEVER.

OBJECTIONS CONSIDERED—STATISTICS REVIEWED.

PLEURISY offers an indication for cessation of the baths, because it demands rest. If, however, the temperature be persistently high, and nervous symptoms threatening, these must be combated by the bath, even though pleurisy be present.

Brand has never observed pleurisy in his 335 cases; Rolet in 1005 cases only four; Mollière only one in 234 cases. According to Betke the mortality from the complication, which is rare in the cases treated by the bath, is only 0.20 per cent. in 5,075; while in 1,420 cases treated medicinally it was 1.4 per. cent.

Severe cough and paroxysms of dyspnœa are not rare, when patients feel the first shock of the bath. But these symptoms soon subside. T. and B. mention five cases in which it persisted so as to require abstention from baths. In some cases the oppression of breathing is voluntary; the patient either imagines it, or he simulates it in order to alarm the attendant and prevent a continuation of the bath. By reassuring such patients, the fear may be overcome. If cyanosis and syncope occur, the bath must be discontinued, but in severe cases this should not deter us from renewing it. The graduated bath or the wet pack sometimes helps these cases. The cough is advantageous, as it relieves the bronchial tubes of mucus and stimulates the pulmonary circulation.

Hoarseness does not forbid the bath, but *œdema of the glottis* and *pericarditis* do.

Collapse is a contra-indication to the strict cold bath, but may be effectively met as has been referred to in a preceding article, by the warm half bath, with cold affusions.

Syncope and fainting have been charged as causes of death due to cold bathing. A large experience readily disposes of this bugbear. Death from sudden heart failure is not an unusual occurence in typhoid fever; the cold bath is, as I have shown, the best weapon against it. Koerber has shown that in 874 cases of typhoid treated by cold baths, only 10 died immediately after the bath, and these were very desperate cases. "What may be especially dwelt upon, is the fact," says Vogl, "that in thousands of baths not a single time was collapse to be observed; either before, during, or after the bath."

Albuminuria, infectious nephritis, œdema, are not only not a contra-indication to baths, but they are of the greatest value in these complications; they favor diuresis and relieve the kidneys. Only when extensive œdema or anasarca occurs should the baths be discontinued.

Vomiting and colic pains are not rare; they offer no bar to the bath, unless following invariably after it.

Perforation and peritonitis strictly forbid the bath, because the latter involves disturbance of rest.

The claim that these serious complications are sometimes due to the bathing has not only been refuted by abundant and convincing statistics with case histories, but the fact has been established that they have been reduced in frequency. Murchison's statistics of 1,271 cases give 196 cases of perforation (11.38 per cent.) Brand's 4,884 cases give 12 perforations (0.24 per cent.)

Intestinal hemorrhage when severe and accompanied by general symptoms, such as pallor, small pulse, cold extremities, subnormal temperature, forbid the continuance of the bath. A slight discoloration of the stools need not deter the attendant from continuing the baths. Brand has continued them in six cases with good effect. He distinguishes the congestive hemorrhage which occurs mostly before the fifteenth day, and which does not forbid the bath, from that occurring later and due to diseased action in the bloodvessels proper. If the hemorrhage is pronounced, rest is imperative and this alone requires abstention from the bath, which, however, may be again resumed, so soon as the hemorrhage is stayed, if the intensity of the fever demands it. Indeed this should be a rule in all cases in which the bath has been suspended for a cause, for to it may we entrust the invigoration of the patient which alone can tide him over the ever present dangers due to the fever processes. Free perspiration does not contra-indicate the bath. The patient should be dried with friction before being placed in it.

Bedsores forbid the bath (if large) because disturbance of the patient interferes with a strict antiseptic treatment. General ablutions and cold compresses should be substituted.

Erysipelas does not present a reason for discontinuing baths, so long as there is no extensive destruction of tissue accompanying it.

Late cases—viz., cases coming under treatment after the second or third week—do not forbid the bath. Although the effect of the latter will not be striking, and the prognosis cannot be expressed as favorable, hospital histories demonstrate that many desperate cases, which under medicinal or expectant treatment were formerly lost, now recover under judicious hydriatic treatment. The condition of the heart is the chief index to the bath or rather to the kind of bath. To react from a bath at 65°, a certain integrity of the central nervous system and of the heart muscle is required. This is almost surely impaired by a long continued febrile process, even if no actual organic degenerations have been developed. Hence the graduated bath of Ziemssen or the wet pack is more applicable, or a warm bath with cold affusions, followed by friction. These may restore the lost stamina and enable us to resort to the cold bath, if the symptoms demand it.

The analogy between the treatment of typhoid fever by strict cold bathing and the treatment of severe types of malarial fever by quinine is so striking that I desire to call attention to it, in order to illustrate the necessity of precise attention to detail. Any one who has, like myself, treated a large num-

ber of cases of the severe types of bilious remittent and congestive fevers on the Southern river banks, has realized how important it is to cinchonize the patient at the earliest possible moment, in order to prevent the recurrence of the paroxysm, which brings parenchymatous changes in its train. When the latter are once established, the fever continues despite the best directed administration of quinine. The antagonistic specific effect of quinine is no longer required; we have a hepatitis, a gastritis, or splenic enlargement to treat, with which we are unable to cope successfully. But if the malarial element be not wisely met by quinine, the patient will surely die from the combination of the malarial and parenchymatous diseases. So it is with typhoid fever. The cold bath represents the effect of quinine in malarial fevers: although it has not the specific antidotal effect, the cold bath, applied in the early stage, has the same prophylactic effect in preventing parenchymatous degenerations. If the latter have occurred, by reason of the neglect of the cold bath, we are called upon to meet them by stimulants, rest, etc.; but at the same time we may resort with advantage to some modification of the bath as a potent auxiliary.

One correspondent requests an opinion regarding the substitution of the cold pack for the bath. "What theoretical or practical reason," says she, "is there for considering (at least until tried in the individual case) that the cold pack, repeated every ten minutes for a time, will not act as an antipyretic and stimulant as successfully as the bath?" There are both theoretical and practical reasons to establish the inferiority of the pack. As an antipyretic, the cooling effect of the pack is limited to the first few minutes; the vessels are rapidly contracted by the shock to the peripheral nerves; the cooled blood is sent to the interior only until reaction is established. Now, however, the sheet surrounding the heated body rapidly absorbs its heat; there being no accession of cold, as in the bath, the now dilated superficial vessels do not receive cooled blood to carry to the interior, as in the cold bath. A second pack is required. The patient, now warm, his superficial vessels dilated far better than in the cold bath (with friction), is wrapped again in a sheet wrung out of water at 60°. The stimulating effect is pronounced; the patient is refreshed; the blood, cooled for a few minutes on the surface, rapidly diffuses its lowered temperature in the interior. But very soon equalization of temperature between the body and sheet take place, which, according to experiment, requires about ten minutes. A third and a fourth pack must be resorted to, each one reducing the temperature slightly by the process above indicated. Liebermeister has demonstrated by actual trial that four successive packs, of ten minutes each, reduce the temperature only as much as a cold bath of ten minutes. Hence it would require about five or six packs to produce the same effect of one of our 65° Brand baths. Aside from the trouble and time, and disturbance of the patient involved in six packs, even if we grant the antipyretic result, the stimulating effect cannot endure, unless the superficial vessels, relaxed as they are by the last pack, are again made to contract by a cold half-bath or ablution. It is a well established principle in hydriatic procedures, never to administer a wet pack without following it by a cold half-bath, because the object of all cold hydriatic procedures is reaction and consequent tonic effect.

The suggestion of my correspondent, however, is not without value, for the wet pack is a valuable auxiliary to treatment in those cases in which, by reason of great debility or marked antipathy to the cold bath or unpleasant effect of the latter, a substitute is required.

In children under ten years old, the bath at 65° should be administered with caution, gradually lowering the temperature of each bath, to ascertain the reactive capacity and resistance of the fever. In these patients the wet pack and graduated bath are valuable auxiliaries.

It will be observed that while the rule to bathe every case of typhoid or suspected typhoid regularly every three hours in water at 65°, whenever the body temperature reaches 103° in the mouth, is to be rigidly followed, there are conditions referable to the patient, or to the type and stage of the disease, which in hydriatic treatment demand as judicious modifications as in every other valuable therapeutic application. On the other hand, the more thoroughly we become familiar with the cold bath treatment, the more rare will be the apparent indications for modifying the temperature or quality of the bath. An accumulated experience will develop a remarkable universality of the rule.

MONTEFIORE HOME, NEW YORK.

C. C. Rice, M.D., att. Laryngologist.

Leo Ettinger, House Physician.

REMARKS ON APPLICATIONS TO LARYNX, ETC., IN CASE OF TUBERCULAR LARYNGITIS.

THIS man has a tubercular ulceration limited to the right vocal cord. In these cases the tubercular infiltration so thickens the cord that it admits of this ulceration. The arytenoids will soon be invaded by the disease. The house physician informs me that the man has pulmonary cavities. In making applications to the larynx, until we have become acquainted with the temperament of his throat we should only use mild applications; the use of strong ones will cause a spasmodic action of the larynx, which in the future may arise almost automatically, whereas if we train the throat we will have less and less trouble at each séance. The landmark in laryngeal application is the tip of the epiglottis; place your applicator on this, then sure of your position, go ahead. The use of cocaine renders topical treatment easy. The epiglottis is of no service as a guide in children; it is small, indistinct and not easy to feel. The arytenoids form a much better landmark; in intubation place your finger on this point, be sure that your tube is in front, and it can then be easily slipped into position. I have intubated in adults by the aid of the laryngoscopic mirror.—K. B. P.

THE CEREBRAL LOCALIZATIONS.

LIKE the historian of nations, who, in the midst of wearisome chronicles of ceaseless war and monotonous change of dynasties suddenly awakens to a high pitch of eloquence as he describes some wonderful work of man—whether it be the fabrication of a Bayeux tapestry or the discovery of a new continent—so will the future historian of medicine, in the midst of his long and tedious account of unsuccessful grappling with disease, suddenly cause his pages to glow with the fire of his own enthusiasm as he begins to describe the recent researches and discoveries made in regard to the cerebro-spinal nervous system. At last the very citadel of life, the residence of the divine intelligence itself, has been attacked, and it would seem that man need go no higher in his search after the mysterious unknown. The very sacredness surrounding the human intellect was the most potent cause of its own mystery in times past. Men thought and reasoned about its workings, but they never dreamed of looking in upon it during its activity in life. All sorts of notions were advanced and adopted as explanatory of the strange phenomena of mentalization, but not until within the last few years were they attributed to the united, harmonious action of several parts and areas of the encephalic mass, each of which has its own special function to perform. By the discoveries of the latter day neurologists we have, instead of the vain imaginings of the old metaphysicians about spirits and what not, the seat of the mental activities spread out before us like a beautiful mosaic, each minute part of which is absolutely necessary to the completion of the perfect mental picture.

But, after all, some will say, what is the practical value of all these charming discoveries? Can they be utilized in the alleviation of cerebral diseases, and when the attempt is made—as it has frequently been done—is not the rate of mortality almost equal to that of the diseases themselves? The knowledge alone is of inestimable value, were it entirely unavailable for practical purposes; but, fortunately, it is available, and though the results of cerebral surgery are not at first sight very gratifying, they are fast becoming more so. Men who croak over the beginnings of every advance in science are legion, and will always abound; but sooner or later they, with their croakings, are put to shame by the perseverance, earnest enthusiasm, and final success of those who, in the end, are the real benefactors of mankind. Who does not recall the early struggles of gynæcology, its miserable failures, its bungling operations, and its final contest with ignorant, unprogressive detractors? And yet, where is the surgeon to-day who is not craving to associate himself with the brilliant successes that are being achieved in this department of medicine? Those who long ago scowled at McDowell and Sims, are now like to bring their great work into ridicule in their wild rush to follow where these bold spirits led, for, as has been aptly said: one would almost think, by reading modern medical literature, that woman had no organs outside of the pelvis. Such will doubtless be the experience of brain surgery before it has gained its highest successes; but in the meantime let the magnificent work go on, and for the sake of humanity let it not stop until the very last atom of truth has been discovered and made available for the healing of the nations.

The most recent complete resumé of the subject is the paper entitled "Cerebral Localization in its Practical Relations," by Dr. Charles K. Mills, and read before the Congress of American Physicians and Surgeons at Washington, September 19, 1889. In the early part of the present century Gall, Bouillaud, and Broca located certain special functions, basing their views entirely upon clinical and pathological phenomena. Broca's speech center has remained undisputed to the present day. J. Hughlings-Jackson, in 1864, suggested that certain convolutions gave rise to certain movements which are under the immediate control of the mind. This suggestion was shortly followed by the researches of Fritsch and Hitzig, which settled to a certainty the truth of the localization theory, and gave immortality to their own names. Putnam and Braun, unknown to each other, were performing similar experiments, and arriving at similar results, in the year 1874. These investigators exposed the brain in the dog, and with the minimal current strength of electricity obtained certain definite movements. They then removed a slice of the cortex and, upon a reapplication of the current, obtained no response. Turning back the cortical flap and applying a slightly increased current to the surface, still intact, the same muscular contractions were reproduced. The separate researches of Weir Mitchell, Burdon-Sanderson, Bartholow, Wood, Ott, and others, as well as the clinical studies of Sir Crichton-Brown, Spitzka, Starr, Seguin, Park, and

Macewen, had all tended to strengthen the theory of special cerebral centers. But it remained for Ferrier, Horsley, and Schäfer, who gave special study to this question, and who experimented with lower animals upon a vast scale, to not only establish the correctness of the localization theory, but to quite definitely settle the positions of the various centers. With a few exceptions of minor importance, the views of these observers are generally held at the present day. As with all new discoveries, so here there are opposing views. Goltz follows the teachings of Flourens, and believes that the encephalon is a *single uniform* organ, and that its component parts can only act as a whole. Luys and Munk side with Ferrier in clearly defining the areas of the brain, and so considering the organ as strictly a *composite* one. Others agree with Exner and Luciani in maintaining that there is an overlapping of the centers, so that while their positions may be indicated in a general way, they cannot be sharply separated one from another. This last view is largely based upon the fact that in motor paralysis, due to a lesion of some cortical center, there is an equivalent loss of sensation in the same part. But, as has been aptly argued, the paralysis itself would prevent any expression of pain, even did the animal preserve its sensibility; and furthermore, sensation, whether muscular or cutaneous, is a treacherous symptom at all times to base any reliable observations upon, for people feel differently at different times and under different circumstances. As Dr. Mills declares: "the neurologist and surgeon must, therefore, depend on motor symptoms alone in fixing the site for operation in cases in which motor symptoms are definite. When positive sensory symptoms are present, they should regard these as indicative of the extension of the lesion towards either the limbic lobe or the posterior parietal convolutions; or, the involvement of the fibers going or coming from these gyres in the corona radiata."

Without attempting to go more fully into the subject of localization, for the space of an editorial is far too short to do it, or even the many investigators of it, anything like adequate justice, we will say, generally, that the consensus of opinion places the sensory centers at the posterior and basal lobes of the brain; the motor above the Sylvian and along the Rolandic fissures, and the psychic in the anterior lobes. If man went about on all-fours, as the lower animals do, these centers would correspond pretty nearly to the relative positions of the sensory and motor tracts of the cord.

An interesting question just in this connection is the center for the higher mental faculties and the possibility of localizing the lesion in various forms of insanity. No doubt now remains but that the cortex is itself the organ of the higher faculties; and since mentalization is itself but the combined action of motor and sensory conceptions in the abstract, its seat is in all probability commensurate with the entire cortex. The cortical gray substance, however, is made up of a number of layers, and a few observations seem to faintly indicate that certain of these layers are concerned in the special acts of mentalization.

Dr. Theodore W. Fisher (*American Journal of Insanity* for October, 1889) well says: "The ideational centers have no immediate connection with the action of individual muscles. The will can only control and the mind is only conscious of movement in the mass. Ideation deals with movements as well as sensations in the abstract. As there is a sensorium where sensations are combined and co-ordinated, there is a motorium, containing the organized residua of all past actions, ready to respond to adequate stimulus in any direction."

If the practical results of all this investigation upon cerebral localization were limited only to the cure of brain tumor—that most agonizing affection known to neurology—it would deserve the everlasting consideration of mankind. But relief has followed operations upon the brain, guided by localization, in cyst, fracture, abscess, hemorrhage and discharging cortical areas. Suffering has been mitigated and life saved. Even in circumscribed epilepsy the majority of operators consider the permanent paralysis following excision of a cortical area preferable to the continual epileptic attacks, Macewen notwithstanding. Even cases of insanity in which the lesion could be localized by the prominence of special symptoms have been benefited and cured by operation.

Hence we may be proud of these late achievements of science. The flood of light thrown upon many obscure, so-called functional diseases, that used to be among the opprobria of medicine, has afforded us knowledge worth exulting over, and which will doubtless restore many a wretched victim of pain and misery to perfect or comparative ease and comfort. Neurology, aided by surgery, is rapidly becoming one of the most exact scientific departments of medicine, and out of exact knowledge we are justified in hoping for more exact and favorable results.—L.H.M.

CURE OF HEMORRHOIDS BY EXCISION AND CLOSURE WITH THE BURIED ANIMAL SUTURE.

THE chief feature of the third day of the meeting of the *New York State Medical Association* was the paper by DR. H. O. MARCY, of Boston.

The writer emphasized the views of Mr. Whitehead in regard to the pathological changes usually found in these painful and troublesome affections. It is only by dissection of the parts in the living subject that the extraordinary dilatation of the hemorrhoidal plexus of the veins can be fully appreciated, and this is the essential factor to be eliminated in the process of cure. Dr. Marcy entered into a judicial and elaborate review of the different methods in more common use, condemning the ligature as unsurgical,

viewed from the standpoint of modern wound treatment, in that it necessarily produces necrosis of tissue, with its attendant conditions of fermentative decomposition, liable to cause septic poisoning. It is also tedious and painful, and deals in a blind and uncertain way with an undemonstrated pathological factorage. Because of these objections, generally recognized, the clamp and cautery method is in common use. This Dr. Marcy thought should be relegated to history as a relic of barbarism, for the same general reasons that have caused its disuse in nearly every other wound made by the surgeon. The pain inflicted, the slowness of the healing process, and often the imperfect results, are abundant reasons for desiring a better method.

The injection of hemorrhoids by carbolic acid or other agents to produce their destruction, was a few years ago gladly accepted by the profession as a great improvement. The general consensus of surgical opinion, however, is condemnatory, chiefly because, no matter how carefully applied, the fluid escapes into the tissue where there is the least resistance, and the connective tissue surrounding and supporting the hemorrhoidal plexus is often destroyed—tissues very important to preserve—while the deformed veins, the real pathological factors, remain unchanged, leaving the patient in a worse condition than previous to the injection. Each of the above methods offered illustrations of what should be adopted as a surgical maxim, that blind surgery is bad surgery.

In attempting the radical treatment for the cure of hemorrhoids there is left almost no other method than that of dissection of the hemorrhoidal plexus of veins, recognized by all as the essential pathological factor. The fear of hemorrhage has evidently been the underlying reason why this method has not been more commonly adopted. This, however, Mr. Whitehead has clearly shown by abundant experience is not excessive and need not be considered under any of the ordinary conditions.

In order to control the hemorrhage, Mr. Whitehead is careful to dissect the veins little by little, and follow immediately by interrupted silk sutures co-aptating the skin to the divided mucous membrane.

Dr. Marcy's method is entirely different from that of Mr. Whitehead's, in that he first encircles with a row of continuous tendon sutures the base of the hemorrhoidal plexus before division. This method is briefly given as follows: The etherized patient is placed in a lithotomy position, the sphincter stretched to produce paralysis of the muscle, and the rectum and parts surrounding thoroughly cleansed with the sublimate solution. A pledget of wool, freely dusted with iodoform, is then carried into the rectum. Division is made by knife or scissors along the juncture of the skin and mucous membrane, and the plexus dissected quite down to its base on a line with the external fibers of the sphincter muscle. This is readily done without much loss of blood. The deformed hemorrhoidal plexus is thus separated from its surroundings, except at the base. A needle, with the eye near the point, threaded with tendon is carried behind the mass, emerging beneath the mucous membrane, unthreaded, rethreaded with the opposite end of the tendon, and then withdrawn. In this way the entire base is encircled by a line of deep double continuous sutures. The plexus of vessels is dissected with scissors from just above the line of sutures. The mucous membrane is now stitched by a continuous tendon suture to the line of division first made through the skin. Dr. Marcy prefers a running blind stitch taken from side to side, from within outwards, which also buries the external line of sutures. The operation is conducted with all possible precaution to prevent infection of the parts, irrigation being continued throughout. When coaptation is complete the united edges are carefully dried, dusted with iodoform and covered in with a layer of iodoform collodion. The bowel may be moved subject to the discretion of the operator any time after the third day. Primary union may be expected with resultant rapid cure.

Dr. Marcy's experience has been ample to test thoroughly the method as outlined, and he confidently recommends it to the profession.

COCILLANA.

So numerous have become the new therapeutic resources of the materia medica, that one may almost be justified in passing unnoticed some of them, particularly when they do not promise to accomplish any more than what long-tried remedies have already done. But in regard to cocillana, an exception will probably have to be taken, judging from Dr. David D. Stewart's clinical experience with this drug, as published in the *Medical News* of August 24, 1889.

Sycocarpus Rusbyi (cocillana) belongs to the natural order *anacardiaceæ*, and is a native of Bolivia, whence it was first obtained by Dr. H. H. Rusby, in May, 1886. The bark is the part of the tree employed, out of which a concentrated tincture and fluid extract are manufactured for medicinal use. It has a powerful and unmistakable physiological action which, in some respects, resembles that of ipecac. According to Dr. Rusby (*Thérapeutic Gazette*, August, 1888) it is used by the natives of Bolivia solely for its carthartic and emetic effects. Taken in the crude form it is also a vigorous expectorant. Some of the bark was partially dried in the sun, powdered in a mortar, and administered thus crudely in doses of twenty, thirty, and fifty grains, in three cases respectively; nausea, prostration, sneezing, nasal discharge, metallic taste in the mouth without dryness, diarrhœa, with rectal irritation, dull headache, slight perspiration, and free and profuse expectoration of mucus, were some of the more pronounced symptoms, chief among which were the expectoration, vomiting, and catharsis. Hence it is

suggested that therapeutically cocillana might be used in ordinary acute or chronic nasal catarrh, hay-fever, membranous croup, diphtheria, bronchitis, pneumonia, and allied diseases.

Dr. Stewart has tested the drug in forty cases, comprising ten of acute, one of subacute, and nineteen of chronic bronchitis; five of broncho-pneumonia, and five of phthisis. Nineteen of the patients failed to report. Of the twenty-one remaining, five were of acute, and eleven of chronic bronchitis; four of broncho-pneumonia, and one of phthisis. Some of these cases are related in full in the paper cited. Of the entire twenty-one cases, sixteen were benefited while taking the cocillana, and five of these were cured. Cough, expectoration, night-sweats, anorexia, and constipation were the special symptoms improved. The author's conclusions are, that this new drug is serviceable in bronchial catarrh, especially of the subacute and chronic form.

The dose of the concentrated tincture is from one-quarter to two fluidrachms. This preparation, of which Dr. Stewart used too small a dose to be completely effective, is not so eligible as the fluid extract. This latter preparation, of which we are now making extensive trial, may be administered in doses of ℥vij to ℥xxv every three or four hours. We hope to report our results later, and in the meantime we commend this new and apparently effective remedy to the consideration of our readers.—L.H.M.

Annotations.

CO-EDUCATION.

IN a letter to be found in another column, Mary Putnam Jacobi takes up the question of the Co-education of the Sexes in Medicine, and puts the subject in a new light. She looks on it from the standpoint of the woman who desires a medical education, and finds that the greatest advantages, the best teachers, are to be found in the schools appropriated exclusively to men. In fact, when we ask the question, Why does the student attend college at all, instead of studying his text-books at home? we reply that he goes there to hear the interpretation of these books, illustrated by the experience of those who teach. He chooses the college where the teachers are to be found whom he prefers; whom he believes best capable of imparting knowledge, or whose personal character gives most weight to their precepts. This freedom of choice as to preceptors the female student also asks; and we cannot denominate her demand as improper or unreasonable. But we think that Dr. Jacobi has limited too closely the field in which co-education would be inexpedient. As a teacher in medicine, we feel that the presence of women among our class of young men would be objectionable very frequently in the discussion of the etiology of disease—especially in the department of nervous diseases—and we believe that, as the course proceeded, it would be found that a large number of the subjects treated under the head of practice would be preferably delivered to the sexes in separate classes. Whether it is not the duty of an institution chartered by the State to provide facilities for the instruction of women, when they formally demand it, is a matter which might well bear investigation.

While with the exceptional man and woman, who think only of the noble profession to which they feel that they have been called, the freest co-education might present no difficulties, yet, in dealing with the great majority of those who fill the benches of our college classes, this would not be the case. It is only the few who feel the divine afflatus; the many are of the earth, earthy.

TREATMENT OF NEURASTHENIA.

THE treatment of neurasthenia is ably discussed by Prof. L. Hirt in the *Wien. Med. Presse*, Sept. 15. From two factors especially, he says, great things may be expected in neurasthenia: viz., electricity and water, preferably cold water. We may well say that the former offers no such beautiful results in any other nervous affection. Beard and Rockwell's general faradization is to be decidedly preferred, especially with the brush to be applied on every part except the head. The effect is striking; the patients, though unpleasantly affected by the application, feel themselves decidedly strengthened, and leave the physician as if newly born. The cold-water treatment of neurasthenia requires more care than in any other disease. He warns against excesses; the enfeebled, easily excited patients do not bear low temperatures well; they become sleepless, and the effect is negative. But with medium temperatures, 77° to 86° F., cautiously made by light rubbings with the wet sheet, brief affusions and cold, brief, sitz and half baths, avoiding douches altogether, the results are encouraging, if continued eight to ten weeks.

SUGAR FOR WOUND TREATMENT.

IN the Strasburg Clinic this well known "preservative agent" has been utilized as an iodoform sugar (one part of iodoform to ten of sugar), in the treatment of specific tubercular processes, and as pure sugar for ordinary wounds. The application is made by bags filled with sugar, which usually remain in situ six to eight days. It is also sprinkled upon wounds directly, in order to cleanse them of acid, deodorize them, and thus produce healthy granulation. Sugar does not possess antiseptic properties, but it is used as an absorbent of secretion and as a protection against infection from without, after purification by sublimate. Lactic acid is developed by its admixture with the fluids exuding from the wound, producing an acid reaction in which most bacteria fail to germinate.

Amputations, resections, complicated fractures, necrotomies, etc., were thus treated. The results would justify the conclusion that the sugar dressing is entitled to a position among other wound dressings, and that it may be preferred to others, because almost all wounds take a very favorable course under it, and it is, moreover, cheap and everywhere procured. —*Wiener Medical Presse*, No. 36.

Society Notes.

JEFFERSON COUNTY MEDICAL SOCIETY, ALABAMA.

Stated meeting August, 1889.

W. E. B. DAVIS, M.D., in the Chair.

DR. WILSON reported a case of

LEUCOCYTHEMIA

in a negro, aged twenty-one years. He had not had good health for four years. December, 1888, he began to have pains in the legs and got so much worse, that he was admitted to the County Hospital in January. At that time he had frequent hemorrhages from mucous membranes, was very anæmic, and gave a history of syphilis. He improved very rapidly under iodide of iron and was discharged. He improved after a few weeks treatment, but was readmitted in May with profound anæmia and some splenic enlargement. The heart murmurs were soft. He had been treated during this time with iron. He was now put on iodide of potassium without any perceptible benefit. A rough estimate of the blood corpuscles indicated both a relative and actual diminution of the red. An accurate estimate of the red and white blood corpuscles, the doctor thought, would furnish a positive diagnosis of leucocythemia.

In the discussion DR. J. D. GIBSON asked Dr. Wilson if there were present any petechial spots on the body, and if there was any hemorrhage of the internal viscera. He also raised a doubt as to the diagnosis of this case as there was no enlargement of the spleen. He discussed its relations in connection with hemorrhagic purpura.

DR. PARKE said, that Dr. Wilson's case was of decided interest to him, and while he concurred in the diagnosis of leucocythemia, he could not be certain in the diagnosis. To his mind it lay between leucocythemia, pernicious anæmia and the profound anæmia occasionally found in syphilis. He had examined the blood on two occasions, but not having the proper apparatus for counting the corpuscles, was not able to say definitely whether there was an apparent or real increase of the leucocytes. In watching this case, he had been impressed with an idea recently advanced by Mr. Jonathan Hutchinson, that in the evolution of disease, these marked cases are merely further advanced along the line of some simple disease. In this class there would be simple anæmia-chlorosis, pernicious anæmia and leucocythemia.

DR. JOHN D. S. DAVIS reported a case of

ILEO-COLOSTOMY IN WHICH DAVIS' CAT-GUT MATS WERE USED FOR APPROXIMATION.

July 16, 1889, 8 o'clock P.M., his brother, Dr. W. E. B. Davis, was called by Drs. Charles and C. F. Dremen to operate on a negro, aged forty-two years, and a furnace tender, for intestinal obstruction. He found the patient *in extremis*; temperature 101°, pulse 135. He made a diagnosis of peri-typhlitic abscess; suppurative peritonitis, and fæcal obstruction of the ileum, in the region of the ileo-cæcal valve, and expressed the opinion that the man would die in a few hours regardless of any operation.

He opened the abdomen from the symphysis to midway between the umbilicus and ensiform appendix, and found a peri-typhlitic abscess; general peritonitis, due to rupture of abscess sac; compound flexion of ileum—bound by strong adhesions in the region of the ileocæcal valve, and fæcal impaction, accompanied by great distension of intestines above the seat of obstruction. The abdominal cavity and abscess sac were thoroughly cleansed by irrigations of hot water. The ileum was opened near the point of obstruction and emptied of nearly one gallon of impacted fæces, liquids, etc. A second opening was made at the jejuno-ileum juncture, to allow the escape of a large quantity of gas in the upper part of the bowel. These openings were closed by Czerny-Lembert sutures. At this point in the operation the patient seemed to be holding out well; and, to avoid the necessity of resorting to the formation of an artificial anus, he was requested to do an anastomosis by means of his approximation cat-gut mats, with the view of establishing the continuity of the intestines. The ileum, above the seat of obstruction, was brought into communication with the ascending colon, below the point of obstruction, by making one incision, one inch and a half in length, in both intestines at a point opposite the mesenteric attachments, and the visceral wounds carefully united by means of his approximation cat-gut mats. A cat-gut mat, to which was fastened four braided silk threads, was introduced through each opening into the intestines. The lateral sutures were passed through the margins of the wound to prevent ectropium of the sides of the incisions. After the mats and sutures were in place, the wounds were brought in contact and the four sutures tied, which accurately coapted the serous surfaces of both bowels, over an area corresponding to the size of the mats. This procedure occupied only three minutes. No outside safety sutures were made, as the approximation was perfect and the coaptation sutures well protected between the approximation serous surfaces.

A glass drainage-tube was fixed in the lower portion of the wound and the peritoneum closed by a continuous cat-gut suture. Abdominal wall was closed by interrupted silk sutures, and an antiseptic dressing applied. Time occupied in whole operation, sixty-five minutes. The patient rallied nicely, was comfortable, and gave favorable signs of recovery for fourteen hours. Three hours after the operation was completed, the patient had a small fæcal passage, when a large quantity of gas passed per rectum. Temperature, ten hours after operation, 100°, and pulse, 120. Fourteen hours after operation, while unattended by the nurse, the patient attempted to get up by himself, and died suddenly, from exhaustion.

Necropsy two hours after death. Abdominal wound united. Omentum adherent to wound at points of operation and incisions. The anastomosis was perfect, and the new opening sufficiently large to nearly equal in size the lumen of the ileum. Adhesions between the two serous surfaces of the bowel firm, and extended a little beyond the line of approximation—as you can see from the specimen removed at the autopsy.

While this was a desperate case for any operative interference, he was sure that the patient's life was comfortably prolonged ten or twelve hours by the opening, emptying and washing out the abdominal cavity. He expressed his regrets that Dr. Dremon did not see the patient early enough to have been able to give him the benefit of the anastomosis at a time more favorable to recovery. Even at the late hour in his illness, at which the operation was performed, he did not think a better, safer, or easier means for restoring the intestinal continuity could have been had. The specimen which the doctor showed clearly illustrates the possibility of the future popularity of intestinal anastomosis. He is not at all doubtful of the great advantage it possesses, when obstruction exists, over the tedious, difficult, and often fatal operation of circular enterorrhaphy. The mechanical principle is clear, the method practicable, and the application clearly demonstrated. Resections with circular enterorrhaphy, lateral apposition with suturing and plastic operations have had their day (though of little value); the objection to them being a dangerous consumption of time, long exposure to infection, frequent leakage, and abscesses. While the application of the principle to man has yet been limited, the method offers advantages many times as great as the old operations in mortality, and can be applied in one-sixth of the time.

Intestinal anastomosis undoubtedly appeals to the practical surgeon, and will find greater favor every day; and it is no jejune proposition that its appeal to favor rests on the technique of the operative procedure, rather than upon the basis of inductive logic that has that mixture of a small amount of truth with a large amount of error which gives so many popular procedures their temporary plausibility and mischievous tendency.

He gave a description of how to make his catgut mats,[1] and demonstrated on the dog how easily they could be applied. He exhibited a dog, weighing twenty-five pounds, on which he had done three laparotomies—one for omental grafting and two for anastomosis. He also stated that the catgut mats, if not already on hand, could be made by the most ignorant nurse in one hour, of any desirable size.

Discussion.—Dr. W. E. B. Davis said that he agreed with the author of the paper that his catgut mats were superior to Senn's decalcified bone plates and Abbe's catgut rings. He thought the experimentations of the author had proven conclusively that the mats possessed all the qualities claimed for them. Referring to the case reported, he said this was the second case in which he had opened the abdomen three days after symptoms of rupture of a perityphlitic abscess with general suppurative peritonitis. While these were hopeless cases, the operation had given great relief in both instances, and certainly had not shortened the lives of the patients. He had operated in both cases in order to give the patient the benefit of a correct diagnosis, and with the hope that he might find a condition less serious than he had diagnosed. He said that the lesson taught in the reports of these late operations with fatal results was the importance of early diagnosis and prompt operative procedure. He thought if the abdomen could be opened within the first twenty-four hours, that the chances for recovery were favorable. He emphasized the importance of thorough study of perityphlitis by the general practitioner, that the surgeon might be consulted in time to give the patient the benefit of early operation. He favored opening the abdomen even after the third day, in cases of suppurative peritonitis, in order to wash out the cavity and to afford the patient relief; and, too, from the fact that a diagnosis could be made, and perhaps a condition found capable of relief. He cited in favor of exploratory incision a case which had been reported by Dr. Stross at the last meeting of the Society, which he had seen in consultation and advised against an operation, believing the condition to be cancer of the stomach in its last stages. A *post mortem*, however, showed the stomach to be healthy and full of woody fibre, and only needed an operation for its relief. He always operated in cases of perityphlitic abscess.

Dr. Abernethy asked Dr. Davis if he used drainage in such cases as reported.

Dr. J. D. S. Davis said, in his reply to Dr. Abernethy, as to drainage after intestinal anastomosis, that he was guided as in all other abdominal operations. He never put a drainage-tube in when he was able to thoroughly cleanse the abdominal cavity. When conditions existed with the abdominal viscera that necessitate drainage, he put in a blind glass drainage-tube with numerous lateral perforations. This is a device of his own, which he prefers to any other, as there is no distal opening into which the omentum may get and cause trouble; while still it has numerous small holes all around it to sufficiently allow the escape of any collected abdominal fluids. Through it the abdominal cavity may be flushed with sterilized water, and the water withdrawn by gravity without danger of getting air into the cavity.

In general suppurative peritonitis of three days' duration the serous surfaces of the bowel and peritoneal cavity are largely deprived of the endothelial covering, and the washing out of the abdominal cavity is followed by a copious exudation of plastic lymph, which like a cement substance, mechanically agglutinates the numerous coaptated folds of the bowel throughout. These multiple adhesions which bind the bowel in so many flexions can, possibly, be prevented by the early administration of cathartics which tend to relieve the paresis and increase the peristaltic move. And in cases where he thought it impossible after operation to restore the peristaltic move sufficiently to prevent adhesions, he would not hesitate to operate, that the sufferer might have the benefit of the doubt, and also for the purpose of rendering comfortable the dying hours of the patient.

Dr. A. T. Henly presented to the Society

TWO DOUBLE SILK LIGATURES

with the following history: Mrs. T. had suffered for two or three years with ovarian disease. Dr. T.

[1] *Virginia Medical Monthly*, May, 1889, pp. 166 and 167; *Alabama Medical and Surgical Journal*, May, 1889.

Gaillard Thomas performed a laparotomy on her on October 10, 1888, removing both ovaries and tubes. The recovery was uneventful, except that two fistulæ formed in the abdominal wound, and continued to discharge pus of a healthy character. She returned to Birmingham, December 1. During the spring months she suffered very considerable pain in both inguinal regions, with very marked tenderness. Probes could not be introduced more than one inch. In May this pain was very severe. There was no perceptible swelling. About the first of July a portion of a ligature made its appearance at the opening of the lower fistula, but it could not be removed without more force than was thought advisable to use. On 23d of July both ligatures were discharged upon the dressing, and the fistulæ both closed within a few days, leaving her without an ache or pain of any kind, and apparently in perfect health. One of the ligatures is in a perfect condition, the other has been partially absorbed. These ligatures came from the pedicles. In a private letter from Dr. Thomas, written in May, he stated that pedicle ligatures were causing the trouble and predicted that they would be discharged.

Dr. J. D. S. Davis said that he believed the want of success with abdominal silk ligatures was due to insufficient sterilization. That silk thread contains more or less oil from the hands of the workmen, and they must therefore be thoroughly freed from all fatty matter before placing the same in the antiseptic sublimate solution, because, if the oil be present, watery solutions will not act on the thread to render it aseptic. He kept all ligatures in chloroform or ether for twelve hours before using them, then shakes well and immerses in 95 per cent. alcohol—leaves for twelve hours, and then transfers, while still moist to 1–1000 watery sublimate solution in which they may be allowed to remain for twenty-four hours. After taking from the bichloride solution, he allowed them to dry, and then rolled in sterilized linen compresses, and placed in a suitable glass bottle, or 95 per cent. alcohol, to keep.

He holds that the main object is to free the silk from all fat and oil before sterilization. And when ligatures for the abdominal cavity are thus rendered aseptic they are not liable to produce suppuration, or secondary abscess, though otherwise primary abscesses would necessarily be the result.

Dr. W. E. B. Davis considered the silk ligatures a frequent cause of pelvic abscess. He also reported a case in which he had removed the ovaries and tubes, *nine* months ago, and stated that the patient had recently had an abscess due to the ligatures which opened into the vagina. He also referred to a case operated on three weeks ago, in which the ligatures had caused an abscess which opened through the rectum, after which the patient did well. While he recognized the silk as more liable to be followed by this complication, yet he considered it decidedly the safest ligature to use. He agreed with Dr. Goodell that cat-gut would soon bring one to grief in the loss of a patient from hemorrhages.

Japan has thirty-one schools of medicine, one of dentistry and two of veterinary surgery.

Letters to the Editor.

CO-EDUCATION IN MEDICINE.

WILL you permit me to make a remark in relation to the question of co-education in medicine, discussed in your columns on October 12th?

The difficulties in such education arising from considerations of delicacy only occur in connection with a limited range of subjects—namely, the anatomy, physiology and diseases of the sexual organs. It is perfectly feasible to give separate instruction on these subjects to classes who are united in the instruction of other branches of the curriculum, didactic or clinical, and who are submitted to the same test examinations.

It would also be desirable to have separate laboratories for dissecting and other practical work.

With such provisions, which are not at all difficult to carry out, it is not easy to see how any objection to medical co-education could arise on the score of delicacy.

It is not necessary to suspect illegitimate motives in the women who seek professional education in the schools hitherto devoted exclusively to men students. Women seek these schools because in them alone can they find the solid traditions, the complete intellectual horizons which have been developing during centuries of exclusive masculine prerogative. Denied the advantage of such schools in their own country, American women by scores expatriate themselves every year in order to enter European universities. Although no provision is made in these for separate instruction on any subject, it is perfectly practicable, as I know from personal experience, to spend several years in hospitals and medical classes, yet to completely avoid the few subjects that might justly embarrass a young woman in the midst of a class of men. Such avoidance would be still easier and cause much less sacrifice of valuable opportunities if European clinics were habitually conducted with the decency which American public opinion demands for the sake of the patients.

Women's colleges are needed to provide special drill, oversight, and in some directions instruction. But each should constitute an annex to a university, intended for the highest instruction of studious youth irrespective of sex. I confidently look forward to the time when this will be the case, and consider it a distinct misfortune that any other system has ever prevailed.

Mary Putnam Jacobi.

New York.

Cincinnati Letter.

AT the recent contest for the positions of externes, at the Cincinnati Hospital, becoming internes after a period of six months' service, there were fourteen candidates—eight from the Medical College of Ohio, and six from the Miami Medical College. Messrs. Landis, Mussey, Freiburg, Bettman, Brady, and Morris were the successful candidates from the Ohio College, and Mr. Morris from the Miami Medical College.

The *Daily Commercial Gazette*, of this city, found so much news in a recent Cincinnati letter in the TIMES AND REGISTER, that it published almost the whole correspondence.

The new amphitheatre at the Cincinnati Hospital, which is to seat 600 students, is completed and ready for use. It is quite an addition to the teaching facilities of the city.

Dr. H. Longstreet Taylor has succeeded Dr. A. B. Thrasher as editor of the *Cincinnati Medical Journal*. Dr. Thrasher, who has been editor of the journal since its foundation, four years ago, has found other duties very urgent, and was compelled to relinquish some part of his labors.

Dr. W. W. Dawson, last ex-President of the American Medical Association, has been made consulting surgeon to the Cincinnati Hospital.

Dr. J. C. McMechan has long been known as one of the most amiable of the profession in Cincinnati, and his many friends will not be surprised to learn that in his ever-readiness to be of service to his friends, he has severely injured the muscle of accommodation.

The Southwestern Ohio Medical Society held its First Semi-Annual Session at the Burnet House, Cincinnati, October 9 and 10, 1889, with the President, Dr. W. A. Campbell, of Eaton, in the chair. Dr. C. G. Comegys, of Cincinnati, made the address of welcome, and Dr. W. A. Campbell, of Eaton, made the Presidential address, in which he spoke of the hopes and desires of the society, and the good it might accomplish. Dr. J. C. Culbertson, of Cincinnati, delivered an address on the Importance of Medical Societies and Organizations, and the Necessity of Doctors Taking a Part in the Affairs of State. Dr. George Goodhue, of Dayton, read a paper on Rhinoplasty, which was discussed by Drs. Connor and Ricketts. Dr. Geo. W. Ryan, of Cincinnati, read on Congenital Luxation of Both Hip-Joints, discussed by Dr. C. Seth Evans, Cincinnati. Dr. A. B. Thrasher, Cincinnati, reported the removal of a cockle burr from the throat of a fifteen-year old girl, where it had remained for five days. The removal was effected by Mackenzie's laryngeal forceps. Dr. H. L. Taylor read on Hæmorrhoids and Fistula, which was discussed by Dr. W. W. Dawson. Dr. B. M. Ricketts, of Cincinnati, read on the subject, Ounce Doses of Iodide of Potassium in Syphilis. Dr. Goodhue reported the case of a young lady who took 1200 grains a day for several weeks, and was cured. Dr. C. H. Von Klein, of Dayton, read on the subject, Hypertrophy, Atrophy, and Deviation of the Nasal Septum, which was discussed by Dr. A. B. Thrasher, of Cincinnati. Dr. Chas. W. Dodd, of Cincinnati, read a paper on The Relation of Ocular to General Diseases. Dr. F. Forchheimer presented a new instrument—hæmatometer—for determining the hæmoglobin. He said this instrument was the only means of determining the difference between anemia and chlorosis. Dr. A. D. Murphy, of Pleasant Plain, read a paper on Digitalis in Acute Pneumonitis in Infants. The paper was discussed by Dr. Goodhue, who favored stimulating treatment in the last stages of pneumonia. Dr. A. W. Ashburn, of Batavia, read a paper on the Therapeutics of Antipyrin. He estimated the drug and its uses very highly, and condemned its indiscriminate use by the laity. Dr. E. W. Mitchell, of Cincinnati, agreed with the essayist in his high opinion of antipyrin, and thought it a very safe antipyretic. In anemic and neurotic women he found the drug had a bad effect. Dr. A. M. Brown, of Cincinnati, had used the drug in all diseases of nervous origin and in diabetes. He thought the drug did not receive the condemnation it deserved. It was whispered about among the doctors that the high mortality of the last typhoid fever epidemic in Cincinnati was due to the use of antipyrin. Dr. W. S. Christopher spoke in a scientific manner on the subject of Digestion. Dr. R. T. Trimble, of New Vienna, read a paper on Puerperal Eclampsia. Dr. A. C. Hawley, of Eaton, read a paper on Abortions, and the subject of the treatment of abortions was discussed by Dr. Gustave Zinke, of Cincinnati. Dr. C. A. L. Reed read a paper on A Case of Ovariotomy with Complications. Dr. R. B. Hall read on Abdominal Section Cases and Remarks. He endorsed early operations, as thereby malignant growth was often prevented and its recurrence was not so liable. Dr. Edwin Ricketts urged early interference. Dr. W. W. Hall, of Springfield, reported a case of Sarcoma of the Pelvis. The paper was discussed by Drs. Longstreet Taylor, Seth Evans, and Rufus B. Hall.

The subject of Diphtheria, which is just at present keeping the Cincinnati doctors from having nothing to do, was fully discussed. Dr. J. T. Whittaker, of Cincinnati, exhibited some diphtheria bacilli under the microscope. Dr. Whittaker discussed the etiology of the disease; Dr. Joseph Eichberg, of Cincinnati, discussed the pathology. Dr. Wm. Carson, of Cincinnati, discussed the identity of croup and diphtheria. Dr. Dan. Millikin, of Hamilton, discussed diphtheria of the genitals. Dr. Dandridge, of Cincinnati, spoke of tracheotomy. Dr. Wm. Johnson, of Cincinnati, discussed intubation. Dr. C. S. Caldwell, of Cincinnati, post diphtheritic paralysis. Dr. P. S. Connor, of Cincinnati, was not partial to tracheotomy in diphtheria.

Book Reviews.

ORTHODONTIA OR MALPOSITION OF THE HUMAN TEETH; ITS PREVENTION AND REMEDY. By S. H. GUILFORD, A.M., D.D.S., Ph.D., Professor of Operative and Prosthetic Dentistry in the Philadelphia Dental College; author of "Nitrous Oxide," etc. Cloth, illustrated, pp. 186. Spangler & Davis, Philadelphia.

No higher praise can be afforded this excellent monograph than the mere statement of the fact that it has been endorsed by the National Association of Dental Faculties, as a text-book for use in the schools of its representation. In these days of weak constitutions and luxurious living, the teeth are among the more important organs of the body to exhibit the general decline. There are so many causes in operation leading to their decay, irregularity and malposition, that it seems almost like a miracle that anyone should possess and preserve a perfect set of teeth

throughout life. Heredity, long retention of the deciduous teeth, their early and injudicious extraction, delayed eruption of the permanent teeth, accidents, habits, etc., are some of the causes of irregularities, the study and connection of which form particularly the subject matter of the present volume. The author has aimed to lead the student, step by step, from the simplest beginning to the more complicated and difficult work of practical treatment, and in so doing, has judiciously adopted the simplest and most direct manner. Part I is headed "Principles Involved," and contains eight chapters upon the causes of irregularity and matters relating thereto. In Part II the materials and various methods employed in correcting irregularities are explained and illustrated in three chapters. Part III is devoted to the specific forms of irregularity and their treatment, consuming in all some additional ten chapters. The illustrations are numerous, admirably drawn, and aid most materially in the understanding of the subject.

Pamphlets.

Extracts from Memoranda Relative to Water Supply and Disease in the City of Philadelphia. Made by DR. CHARLES M. CRESSON. Reprinted from the *Press*, 1889.

Medical Department of University of Wooster. Announcement for 1890. Williams Publishing Company, Cleveland, Ohio.

Evolution in the Causation of Disease. By J. N. BEST, M. D., Rosemont, N. J. Reprinted from the *Lehigh Valley Medical Magazine*, Vol. 1, No. 1.

The Medical Digest.

GUM-CHEWERS paralysis is the latest form of professional neurosis recorded in medical literature.

DR. LE FORT says that microbes are never conveyed in the air, but only by contact with the fingers, instruments, etc.

VALERIANIC ETHER has been used as a stimulant, more particularly for anæmic women subject to fainting fits. It is administered in pearls.

POMADE FOR CHAPPED HANDS.—Lanolin, 100 gm.; paraffin oil, 10 gm.; vanillin, 0.1 gm.; oil of rose, 1 drop. Apply morning and evening.

HYSTERIA IN MEN AND WOMEN.—Dr. Marie, assistant to Prof. Charcot, has been studying the comparative frequency of hysteria in the male and female. Basing his observation upon a large number of statistics, he finds that the disease is rarer in men than in women in the middle and upper classes of society, but in the lowest class the causes such as traumatisms, intoxications, alcoholic and other, are more patent in their influences upon the men. The author concludes with the statement that hysteria in the male is very frequent in the lowest class of society and seems even to be much more frequent than hysteria in the female.—*Revue Médicale.*

CHLORAL IN ECLAMPSIA.—Dr. Blanc, chief of the obstetrical clinic of the Faculty of Lyons, urges the use of chloral in eclampsia in the following manner: Introduce a medium sized œsophageal tube into the stomach through the mouth or nose, opening the former if there be violent contraction with some of the ordinary openers, or some sufficiently hard rounded body, or piece of wood shaped like a cork.—*Lyon Méd.*

TREATMENT OF DIPHTHERIA.—Rondot, of the Faculty of Bordeaux, praises the following treatment for diphtheria. On the one hand there should be local antiseptic treatment as complete as possible, and for this purpose, applications of the sublimate solution (1.500) and salicylic atomizings may be advantageously combined. On the other hand the general treatment should consist in the use of small doses of corrosive sublimate (four to six milligrammes); alcohol and milk; bromide of potassium for the laryngeal spasms; caffeine for the heart failure; and quinine for the elevated temperature. Local and general treatment should always be employed during the course of the diphtheria and even after the performance of tracheotomy.

—*Gazette Hebdomadaire des Sciences Médicales.*

CREASOTE, FORMULÆ FOR THE ADMINISTRATION OF.—Dr. Keferstein (Therap. Monatsch.) gives some very good formulas for the administration of creasote. The one at first recommended by Dr. Bouchardat, and later on by Dr. Frantzel, has been modified by the author as follows:

℞ Creasote . . . . . gr.xx.
Alcohol . . . . . ʒvj.
Cinnamon water . . . . . ʒiij.
Cinnamon syrup . . . . . ʒvj.
M. One teaspoonful three times daily.

For the pill-form the following is recommended:

℞ Creasote . . . . . gr.lx.
Powdered marshmallow root.
Purified licorice . . . . . āā ʒjss.
Mucilage of gum arabic . . . . q.s.
M. Div. in pil. No. cxx. Coat with gelatin.
Sig. One pill three times daily.

In irritative cough and diarrhœa the following is administered:

℞ Creasote . . . . . gr.xxx.
Acetate of lead.
Opium (pure) . . . . . āā gr.v.
Extract of licorice . . . . . ʒjss.
Mucilage of gum arabic . . . . q.s.
M. Div. pill. No. 50. Sig. One pill three times daily.

For children, creasote in the form of the following emulsion seems best adopted:

℞ Creasote . . . . . gr.xx.
Dissolve in almond oil . . . . ℥j.
Gum arabic . . . . . ʒv.
Water. . . . . ʒiij.
M. Make an emulsion and add
Comp. tinct. of orange peel . . . gtt. xv.
Oil of peppermint . . . . . ʒj.
M. One teaspoonful two to five times daily.

For drop doses the author uses the following:

℞ Creasote . . . . . gr. xlv.
Tincture of cinnamon . . . . . ʒj.
M. Fifty drops three times daily in a half a cup of warmed milk or warmed sweetened water, or Malaga wine, etc.

—*Deutsche Med. Wochens.*

ECZEMA.—Wiss (*L'Union Médicale*, No. 139) recommends the following ointment for eczema, especially for the hands: Resorcin, 1 part; vaselin, 20 parts.

PUS IN URINE.—To detect pus in urine, drop enough tincture of guaiac into a specimen to produce a milky appearance; then heat a few moments. The pus will produce a blue tint.

—*National Druggist.*

CREOSOTE EMULSION.—Dr. Charles Eloy gives the following formula in the *Gazette Hebdomadaire*, May 10, 1889:

Oil of sweet almonds	f℥v.
Beechwood creosote	f℥ii.
Mix, and add:	
Gum arabic	℥iii–℥v.
Mint water	f℥xvi.

M. Give from two to five soupspoonfuls a day.

IN certain varieties of rebellious night sweats Henri Huchard commends the use of ergot after ordinary remedies have failed. Give one gramme of the powder at night before retiring, or better still half an hour before the sweat begins. Repeat this dose one or two hours later. Continue the treatment for the succeeding three days. The sweat will be suppressed upon the first or second day. Subcutaneous injections of ergotine in doses of one gramme, or of ergotine in doses of one demi-milligramme may be used.

—*Journal des Praticiens.*

CHRYSAROBIN IN HÆMORRHOIDS.—Dr. Kossobudskii speaks of this drug in high terms, but he differs from Unna in the quantity. Dr. Kossobudskii uses a two and a-half per cent. instead of a five per cent, as Unna prescribes. After washing the swelling with a two per cent. lotion of carbolic, or a one per cent. of creolin, he recommends the following ointment to be applied twice or three times a day:

Chrysarobini	0.8;
Iodoformi	0.3;
Ext. belladonna	0.6;
Vaselin	15.0;—M.

or a suppository may be made with cocoa butter. If bleeding be present, tannin may be combined. Dr. Kossobudskii affirms that pain, smarting, and bleeding will disappear in three or four days.

—*Medical Press and Circular.*

DEATH FROM SUBLIMATE IRRIGATION AFTER ABORTION.—Seven years ago since Tarnier introduced the practice of washing out the vagina with weak corrosive sublimate injections. The results proved satisfactory, and the injections came into vogue in German and English, as well as French, lying-in-hospitals, extending freely into private practice. Like every thorough method of counteracting deadly agencies in the human organism, sublimate irrigation is not free from danger, and although it greatly reduces the death-rate and proportion of puerperal fever cases in long series of labors, some cases of mercurial poisoning will occur in those series, notwithstanding the most careful administration of the remedy. In this country Drs. Dakin and Boxall have published minute observations on mercurialism under the above noted conditions; they appeared in the *Transactions of the Obstetrical Society* for 1886 and 1888. Dr. Legrand read before the Anatomical Society of Paris, in April, a case of twin abortion, retained placenta, and death from acute mercurialism. Between the birth of the first and second child, 10 litres of a 1 in 2,000 solution of sublimate were employed to wash out the uterine cavity, twice at an interval of three hours only. Immediately after each injection of sublimate a 2 per cent. solution of boracic acid was thrown up into the uterine cavity; but sublimate had been several times employed for vaginal injection. After the extraction of the second child, the boracic solution was injected into the uterine cavity. The intra-uterine injections were discontinued, and boracic and carbolic solutions were used for the vagina. A day later gingivitis, salivation, colic, and dysentery set in, and carried off the patient in five days. The kidneys were large, pale, and very œdematous; they contained mercurial salts in solution. The palate was ulcerated; the œsophagus, stomach, and small intestine healthy. The mucous membrane of the entire large intestine was covered with eschars and ulcers, most marked on the summits of rugæ. The ulcers began in the cæcum, were least abundant in the transverse colon, and most marked towards the anus. The above conditions have been noted in many other cases of death after sublimate irrigations in childbed. The kidneys were diseased. Keller, of Berne, has already pointed out the danger of mercurial irrigation when these organs are not healthy. The English authorities just quoted both dwell on this danger. Dr. Legrand relates that the ulcerated intestinal mucosa swarmed with bacteria. This fact, he adds, must make us despair of ensuring intestinal antisepsis by means of corrosive sublimate.

—*British Medical Journal.*

UTERINE TUBERCULOSIS.—An interesting case of primary tubercular disease of the Fallopian tubes has occurred in Professor Lebedeff's wards. The patient, who was the widow of a man who had died of phthisis, was of a cachectic appearance and suffered from amenorrhœa. On examination, a firm, nodulated, intra-abdominal tumor was made out, situate in the space of Douglas. An attempt was made to remove the tumor, but had to be given up as disseminated miliary tubercle was found affecting the peritoneum. The intestines and the uterine appendages, too, were all matted together. Six weeks after the attempted operation, the patient died with symptoms of general tuberculosis. At the post-mortem examination miliary tuberculosis was found affecting the peritoneum, the lungs, the pleuræ, the colon, and the mucous membrane of the uterus. Both the Fallopian tubes were dilated and filled with pus, the epithelium in parts being absent. The intensity of the destructive process was greatest in the tubes, and became less marked towards the periphery. In sections tubercle bacilli were found; there was no tuberculosis, however, in the ovaries, and only the mucous membrane of the uterus was affected.—*Lancet.*

DIPHTHERIA prevails throughout the State of Kentucky.

THE *Detroit Free Press* considers the land flowing with milk and honey a bad place for bilious colic.

IT was reported that small-pox was ravaging Pelee Island, Lake Erie; but there proved to be only one case.

PROF. BOKAI, in the *Lancet*, advocates picrotoxin as an antidote for morphia and a preventive of chloroform asphyxia.

A LADY physician declares that spanking has a harmful effect on children's spines. The want of a safe destination will spare the rod.

A TURIN physician has discovered that criminals, as a class, show a marked preponderance over other persons in respect of partial deafness.

PRESIDENT DE WINTON, of the geographical section of the British Association, states that American climate has improved the physique of the Anglo-Saxon race.

ERRATUM.—On page 569 the proceedings published were those of the New York State Medical *Association*, not Society. The Society is the "New Code" organization.

THE sanitary house-to-house inspection of a portion of the Nineteenth Ward developed 681 nuisances, 29 cases of typhoid fever, 8 of scarlet fever, and 5 of diphtheria, during the past year.

DR. NISSON relates, in the *Magdeburger Zeitung*, that he has extracted a needle, seven centimetres long, from the arm of a man in whose body it had travelled around for thirty years.

IT is proposed to found an Anglo-American Vienna Medical Association for giving information and moral support to English and American doctors and medical students of the Vienna University.

IN a boarding-house in Woodbury, N. J., eighteen persons were evidently sick, with symptoms of poisoning. The true cause could not be discovered, although it was supposed to be from eating oysters.

PROF. LEXIS, of Göttingen, has lately prepared statistics showing that there are in the German universities twice as many students as can hope to make a living by the professions which they are preparing to enter.

DR. ARTHUR BOTTCHER, Emeritus Professor of Pathology and Morbid Anatomy in the University of Dorpat, and at one time co-editor of the *St. Petersburger Medicinische Wochenschrift*, died on July 29, in the fifty-eighth year of his age.

DR. CHARLES L. WEED, of this city, whose death is announced in the thirty-second year of his age, was a well-known oculist. He was born in Columbus, Ohio, and graduated with high honors from Princeton College. He completed his professional studies at Jefferson Medical College in 1883, and went to Berlin, where he carried on some preparatory work. Returning to this city, he became resident physician at the German Hospital. Later he became chief of the Eye Department of the German Hospital, and of the Union Dispensary.

THE whole of the sewage of Paris will soon be used for the purpose of gardening. Gennevillier now absorbs and purifies a third of the Paris sewage water. Achires and Mery will soon utilize the rest.

—*Sanitary News.*

THE physicians in Biddeford, Me., objecting to amputate the foot of a man 80 years old, who was suffering with dry gangrene, the patient performed the operation himself. A doctor had to finish the work; but the man now walks about without the aid of a crutch.

UNDERTAKERS' permits must be obtained during office hours, except in cases of emergency, or when a death occurs after said hours, and the attending physician certifies that it is imperatively necessary to remove the remains from the city before ten o'clock the next morning.

The members of the Société de Médicine Pratique, of Paris, recently visited the Pasteur Institute, where they were received by M. Pasteur himself. The distinguished biologist delivered a short address, in which he spoke of the danger of placing dogs that had been bitten in quarantine for a short time, and then releasing them, instead of having them at once destroyed. This culpable negligence often led to disastrous results. M. Pasteur was particularly emphatic in affirming that rabies are never spontaneous.

THE Dental Department of the Iowa State University had 46 students in 1887, 75 in 1888, and for the present session 110 have been enrolled, while a number of others have been refused for want of room. The State will undoubtedly provide means for increased accommodations before the next term opens. The cause of this influx of students is not difficult to comprehend. The management has been quick to appreciate the value of modern methods in teaching, and not afraid to spend money to secure competent persons to impart instruction in them. Such a course is sure to win success.

THE Hartford Medical Society of Connecticut, which was chartered last winter by the legislature, and given power to hold one hundred thousand dollars' worth of property, has recently organized by electing the following officers: President, Gurdon W. Russell; Vice-President, H. P. Stearns; Secretary, C. E. Taft; Treasurer, C. D. Alton; Censors, S. B. St. John, W. M. Hudson, George R. Shepherd; Trustees, G. W. Russell, A. W. Barrows, M. Storrs. This Society, with true Connecticut thrift, proposes to have given to them a fine building, a fine medical museum and library at an early day. This is the true way to make medical societies popular, by having a permanent home to gather round.

To Contributors and Correspondents.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

EWEN, CLARENCE, Surgeon. Relieved from duty at Madison Barracks. N. Y., and ordered to Willet's Point, N. Y. Par. 10, S. O. 242, A. G. O., October 17, 1889.

GARDNER, EDWIN F., Assistant-Surgeon. Relieved from duty at Fort Lewis, Colo., and ordered to Fort Porter, N. Y. Par. 10, S. O. 242, A. G. O., October 17, 1889.

GIBSON, JOSEPH R., Surgeon. Relieved from duty at Fort Sheridan, Ills., and ordered to Governor's Island, New York Harbor. Par. 10, S. O. 242, A. G. O., October 17, 1889.

MAUS, LOUIS M., Assistant-Surgeon. Relieved from duty at Fort Porter, N. Y., and ordered to Fort Stanton, New Mexico. Par. 10, S. O. 242, A. G. O., October 17, 1889.

Changes in the Medical Corps of the United States Navy for the three weeks ending October 19, 1889.

HARMON, GEORGE E. H., Surgeon. Detached from the U. S. S. Constellation, and ordered to Naval Academy.

LOWNES, C. H. T., Assistant-Surgeon. Detached from the U. S. S. Constellation, and to Naval Academy.

WINSLOW, GEORGE F., Surgeon. Ordered to Marine Rendezvous, Boston.

HENRY, CHARLES P., Assistant-Surgeon. Ordered before the Retiring Board for examination.

BERTOLETTE, D. N., Surgeon. Detached from the Franklin, and ordered to Naval Hospital, Philadelphia.

RUSH, N. H., Passed Assistant-Surgeon. Detached from Naval Hospital, Philadelphia, and ordered to the Saratoga.

HIBBETT, C. T., Passed Assistant-Surgeon. Ordered to the Franklin.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service for the six weeks ended October 5, 1889.

FESSENDEN, C. S. D., Surgeon. Granted leave of absence for thirty days. October 3, 1889.

WYMAN, WALTER, Surgeon. Granted leave of absence for thirty days. September 3 and 21, 1889.

SAWTELLE, H. W., Surgeon. Granted leave of absence for seven days. September 26, 1889.

AUSTIN, H. W., Surgeon. Granted leave of absence for thirty days. September 9 1889.

GASSAWAY, J. M., Surgeon. When relieved at New Orleans, La., to rejoin station at Cairo, Ill. September 30, 1889.

GOLDSBOROUGH, C. B., Surgeon. Leave of absence extended thirty days, on surgeon's certificate of disability. September 16, 1889.

ARMSTRONG, S. T., Passed Assistant-Surgeon. Relieved from duty at New York; ordered to command of service at Cleveland, Ohio. September 17, 1889.

AMES, R. P. M., Passed Assistant-Surgeon. Assigned to duty at New Orleans, La., upon expiration of leave of absence. September 30, 1889.

WHITE, J. H., Passed Assistant-Surgeon. Leave of absence extended thirty days, on surgeon's certificate of disability. September 21, 1889.

NORMAN, FENTON, Assistant-Surgeon. Granted leave of absence for thirty days to take effect when relieved. October 4, 1889.

PETTUS, W. J., Assistant-Surgeon. Ordered to Portland, Me., for temporary duty. September 26, 1889. Granted leave of absence for twenty-six days, to take effect when relieved. October 3, 1889.

KENYOUN, J. J., Assistant-Surgeon. Granted leave of absence for thirty days. September 21, 1889.

VANSANT, JOHN, Surgeon. Granted leave of absence for fifteen days. October 16, 1889.

GOLDSBOROUGH, C. B., Surgeon. Leave of absence extended thirty days, on surgeon's certificate of disability. October 18, 1889.

PERRY, T. B., Assistant-Surgeon. Ordered to temporary duty at San Francisco, Cal. October 15, 1889.

VAUGHAN, G. T., Assistant-Surgeon. When relieved, to proceed to Evansville, Ind., for temporary duty. October 9, 1889.

Medical Index.

We purpose on this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Abortion, Anonym. Medico-Legal Journal, September, 1889, N.Y.

A malignant tumor in an umbilical hernial sac, with remarks on the aetiology of cancer, Daniel Lewis, M.D., New York. N.Y. Medical Record, Oct. 12, 1889.

Contributions to the morphology of the saccharomycete of diabetic urine, J. Parker Smith, L.R.C.P. Lancet, Sept. 21, 1889.

Contribution à l'étude des lesions histologiques de la substance gise dans les encephalites chroniques de l'enfance, par Pilliet. Archives de Neurologie, Sept., 1889.

Contributions to the surgery of the abdomen, J. S. McArdle, F.R.C.S.I. (Concluded.) Dublin Journal of Medical Science, October 1, 1889.

Comparative value of antipyrin, antifebrin, and phenacetin, as antipyretics, Surgeon-Major A. Crombie, M.D. The Practitioner, Oct., 1889.

Difficult diagnosis, J. Mitchell Bruce, M.D. The Practitioner, Oct., 1889.

Discussion on the treatment of immature cataract. Brit. Med. Jour., Sept. 28, 1889.

Des antiseptiques locaux dans le traitement de la syphilis, per M. Hallopeau. La France Médicale, Oct. 3, 1889.

De l'intervention chirurgicale dans le traitement des tumeurs cérébrales, par le Dr. Thomas. Revue Médicale de la Suisse Romande, Sept. 20, 1889.

Deux cas d'osteomyelite infectieuse ayant comme portes d'entrée: l'une lymphangite d'original traumatique, l'autre une blennorrhagie ancienne (suite), par le Dr. Cauchoix. La Normandie Medicale, Oct. 1, 1889.

Du chloral et de ses dérivés au point de vue chimique, thérapeutique et pharmaceutique, par Yvon. Archives de Neurologie, Sept., 1889.

Des traumatismes du crâne dans leurs rapports avec l'alienation mentale, par Christian. Archives de Neurologie, Sept., 1889

Discussion on fibrinous membranes within the spinal canal, occurring in general paralysis, Joseph Wigglesworth, M.D., R. Percy Smith, M.D., and Prof. Auguste Vorsin, M.D., British Medical Journal, Sept. 21, 1889.

Electricity and the death penalty, Clark Bell, Esq., Medico-Legal Journal, Sept., 1889, N.Y.

Essay on the functions of indifferent cells in the human organism, James Dickinson. Lancet, Sept. 21, 1889.

Epilepsie somnambuliques avec accidents cataleptiformes, par le Dr. A. Paris. Archives de Neurologie, Sept., 1889.

Etude physiologique et thérapeutique du massage de l'abdomen. Son action sur la diurese, par le Dr. Rubens Hirschberg. Bulletin Général de Thérapeutique, Sept. 30, 1889.

Etudes sur les centres psychomoteurs chez l'enfant et les animaux nouveau-nés, par P. Langlois et R. Romme. La Tribune Médicale, Sept. 26, 1889.

Ice spoils fish, J. Lawrence-Hamilton, M.R.C.S. (No. III.) Lancet, Sept. 21, 1889.

Infantile ophthalmia (blennorrhœa neonatorum) and its prevention, Karl Grossman, M.D. Brit. Medical Journal, Sept. 28, 1889.

Influence of massage on the rate of absorption from the intestine, A. Symons Eccles, M.B. The Practitioner, Oct., 1889

Introduction to discussion on the treatment of glaucoma, Jonathan Hutchinson, F.R.C.S. L.E.D., etc. Brit. Medical Journal, Sept. 28, 1889.

Les maladies et les passions, par le Dr. Sorel. La Normandie Médicale, Oct. 1, 1889.

Monomania, Clark Bell, Esq., Pres., Medico-Legal Journal Sept., 1889, N.Y.

Medical Expertism, S. Gold First, Esq. Medico-Legal Jour. Sept., 1889.

Myxœdema ou cachexie pachydermique (Charcot), par Kovalevsky. Archives de Neurologie, Sept, 1889.

Mineral waters of Brides-les-Bains, C. E. Fitz-Gerald, M.D. Brit. Med. Journal, Oct. 5, 1889.

Notes of a case of sclerotitis, apparently of dental origin, John Hern, M.D. Brit. Med, Journal, Sept. 28, 1889.

Note on treatment of tinea tonsurans, H. S. Prudon, M.D. Dublin Journal of Medical Science, Oct. 1, 1889.

Pyo-salpinx, with remarks on the old faith and the new regarding parametritis and perimetritis, John W. Taylor, F.R.C.S. Lancet, Sept. 21, 1889.

Pyosalpinx, points in the diagnosis of, Hatt. The American Lancet, Oct, 1889.

Posterior dislocation of both bones of the forearm, on the mechanism of, accompanied by fracture of the external condyle, with remarks as to the treatment of old posterior elbow dislocations, Fischer. Amer. Practitioner, Oct., 1889.

Primary lithotomy in Russia, Idelsen. Annals of Surgery. Sept., 1889.

Perityphlitis in children, Huber. Archives of Pediatrics. Oct, 1889.

Pigment in the negro, notes on the formation of, Morrison. Med. News, Oct 12, 1889.

Periostitis of the ribs after typhoid fever, Potter. Pacific Medical Journal, Oct., 1889.

Prolapsus ani and its treatment, James. Hospital Gazette, Sept. 28, 1899.

Physical training of the insane. American Journal of Insanity, Oct., 1889.

Physical training of the insane, remarks on, Adams. *Ibid.*

Physical exercise, Benson. Southern Clinic, Oct., 1889.

Peritoneal effusions after intra-peritoneal operations, a few considerations on, Myers. Cin. Lancet Clinic. Oct. 5, 1889.

Pseudo muscular hypertrophy, Lyman. American Practitioner, Oct., 1889.

Phthisis pulmonalis, a case of, with uncontrollable nasal hæmorrhages, Robison. *Ibid.*

Phantom pregnancy, Stone. Omaha Clinic, Sept., 1889.

Pathology and treatment of disease of the naso-pharynx, some points in the, Mackenzie. N.Y Med. Jour., Oct. 5, 1889

Clinical Lecture.

(Delivered in the Medico-Chirurgical College.)

BY WILLIAM F. WAUGH, M.D,

Professor of Practice and of Clinical Medicine.

Reported by WILLIAM BLAIR STEWART.

ANÆMIA.

THE first case I bring before you to-day is this young woman, who is suffering from extreme anæmia. During the past four weeks she has grown very pale and feeble. She has constipation, headache, and a tendency to vertigo. She has partial amenorrhœa, no disorder of the heart or kidneys, and the lungs are sound and healthy. The sickness at the stomach and dizziness are due to cerebral anæmia. The foundation of this young woman's trouble is constipation. It is not uncommon for her bowels to remain inactive for three weeks. You will not find ten per cent. of such cases of women who are devoid of anæmia. In constipation we have a re-absorption of the liquid portion of the fæces in the intestines, and this vitiates the blood and causes a debilitating effect and a consequent anæmia.

Naturally, this class of anæmic patients needs iron; but if the trouble is due to constipation, what could you expect from iron? There is also here some slight amenorrhœa, which is quite natural in the present state of her health. There is one cathartic that is suitable above all others in these cases associated with amenorrhœa, and that remedy is aloes, given in doses of gr. ss–j. You hear of physicians giving from gr. v–xx, but this is entirely too much. I do not know of any case where more than gr. ½–j of this valuable remedy is necessary. This patient also needs iron, and almost any of its numerous preparations will answer if given in large or full doses. We will order her a pill containing aloes, gr. ½, every morning before breakfast, and as often as necessary to produce one good, regular passage each day. In this way we will overcome the constipation. She will also take of the double tartrate of iron and potassium gr. xx after each meal. Besides this, she not only needs to have her appetite increased, but to insure her digestion. We will give her digestants for her food and not as medicines. Pepsin, pancreatine, and diastase are the three that go to make up the digestants; so we will give a mixture of these, as there is in this case no special failure in the power of digesting any one class of aliments, but rather a general indigestion. Order her the maltine containing pepsin and pancreatin, and use a tablespoonful of this three times daily. As diastase acts only in alkaline, and pepsin in acid solution, it would seem as if they should be given at different times; but practically pepsin, given at any time, will act at the proper place and moment; so that we will give them at the beginning of each meal. We will let her commence each meal with bread, on which is spread this thick maltine—like molasses.

INTESTINAL ULCER.

Our next case has a history, as follows: This man, aged 34 years, an American, and laborer by occupation, came to us complaining that his bowels were moved every other day, and that a considerable quantity of bright-red blood was passed each time for the past three weeks. He has some cough, night sweats, and has had headache for a week. Examination excluded fistula and hemorrhoids. He has pain in the small of his back; has always had constipation, which was probably due to neglect in attending

to nature's calls. The constant use of cathartics weakens the action of the bowels and begets a paretic condition of the same. They become sluggish ; their vitality is lost as well as their sensitiveness. The intestinal muscles become feeble ; saccules are formed, and the lodging fæces cause ulceration, with an accompanying hemorrhage. Pain in the back is only a reflex symptom. This man has an ulcer somewhere in the intestinal canal. It is not in the rectum, as it would cause dysentery, and this symptom is not present. It is not in the small intestine, because blood coming from there would be tarry, unless in enormous quantities. It was thought that hemorrhoids were present, but they were not discovered. In speaking of hemorrhoids, I am reminded of a woman who thought she was dying of consumption. Lung signs were negative ; blood was found in the stools, and examination showed a number of internal hemorrhoids, which were cured by a simple injection of carbolic acid She got well of her "consumption" at once. This man's trouble is in the sigmoid flexure of the colon, or near it.

In the first place, you must remove all hard fæces, as a thing that will irritate and cause the ulcer to bleed. Don't give aloes in this case, as it is expulsive and acts on the muscular coats of the rectum and colon. Chloride of ammonium or sulphate of magnesium are good ; but the most certain of all remedies that produce liquid stools is glycerine, introduced per rectum. Add nitrate of silver, gr. v to hot water Oj, and inject once a day through a long, flexible catheter, passed well up into the bowel to reach the ulcer. We will also give him magnesium sulphate, gr. xxx, in a glass of water, each morning, and have him pass his fæces at a regular time each day. We can also apply a local remedy through the fæces, and it is the best when the patient can endure it. This remedy is turpentine ; ɱx–xx three times a day. If we succeed in curing this ulcer, we must teach the patient good habits. As to food? He must use no jam, containing seeds ; no oat-meal or corn-meal, and no fibrous matter. Let his diet be bland and mild—such as milk, eggs, bread, rice, lean meat, and all food that cannot mechanically injure the ulcer.

HEPATIC CIRRHOSIS.

This man, aged thirty-seven, an American, and railroader by occupation, complains of a heavy weight and pain in the right side of his abdomen. There is no difficulty in micturition. The bowels are constipated. He has a bad taste in his mouth on rising in the morning ; he spits up large quantities of phlegm, and vomits frequently. He is a drinker of alcoholic liquors, but does not use tobacco. He catches cold easily. He complains of pain extending up along the ascending colon, sharp in character. Typhlitis might cause this, but on examination I do not find the firm, sausage-shaped mass which is characteristic of that affection, and will, therefore, exclude it from our diagnosis. Percussion shows that the liver is uniformly enlarged, and extends two inches below the margin of the rib. This condition is known as the hyperæmic stage of cirrhosis of the liver, caused by using alcoholics. In the treatment of these cases the first indication is to stop all use of alcohol. Apply blisters over the liver, and in addition give ammonium chloride, gr. v, three times a day.

CHRONIC DESQUAMATIVE NEPHRITIS.

I have here a specimen of urine to show you, and it is unusual in one respect. The case is one of a boy three years old, who developed a dropsy of the legs six months ago. At present the abdomen is much swollen. The heart is right and presents no murmurs. We cannot look for cirrhosis of the liver at his age. His trouble is in the kidneys, and is evidently one of the three forms of Bright's disease. Which form is it? Amyloid kidney is found in syphilis, and necrosis of bone. In one case I found it due to a chronic otorrhœa. I do not think it is ever caused by caries of the teeth. This case presents no history of syphilis or caries ; and as amyloid kidney is also attended with enlarged liver and spleen, without ascites, we may exclude it.

In the granular contracted kidney there is very little dropsy, which is local without any obvious reason, and transitory. There is, besides this, little if any albumen in the urine. Unlike this, we find here the large quantity of albumen characteristic of chronic desquamative nephritis. When you test urine the specimen should be the first that is passed in the morning after rising, and not after drinking or eating, which alters its character. Ordinarily I fill the test tube to the top, and boil the upper part, so that one may compare the upper hot layers with the cold layers at the bottom. Heating reveals such a large quantity of albumen in this case, that I may turn the tube almost upside down without spilling the fluid. Nitric acid confirms the first test. It is rare that you find as much albumen as in this instance. As to the cause in this case, there is considerable obscurity. The mother says the child never had scarlet fever, as it never was sick a day of its life. Probably it has come from taking cold. The prognosis in these cases is rather precarious. If the microscope shows fatty tube casts, with degenerated epithelium, it is bad ; but if the epithelial cells are not degenerated, it is not so bad, for the patient may recover; with a weakness or loss of a part of the capacity of one or both kidneys.

By keeping the bowels open thrice daily, and giving acetate of potassium, gr. iij, repeated every four hours, with plenty of water, we relieve the kidneys of some of their work. Give good nourishment and avoid all condiments and volatile oils. The skim milk treatment is admirable, for in it we have lactose, which is one of the best of all diuretics ; it also excludes condiments, and gives all the nutriment requisite. Support the strength to avoid hydræmia. Give iron also. Gastric and intestinal catarrh are symptoms due to the circulation of some poison in the blood that affects the status of those regions. In this case we will give tr. ferri chloridi, min. iij. four times a day, before meals. Besides this, there is another important indication, and that is to relieve the kidneys of their labor by putting their work on other organs—the intestines and skin. Give saline laxatives, such as magnesii citras, or sodii phosphas, gr. xx–xxx, in a

plate of soup. Protect the skin constantly from the air, by clothing in wool by night and day. In order to give further protection, rub the boy from head to foot with hot lard every day of his life, and remove the excess with a soft rag. The ancient Greeks used oleaginous inunctions as part of their everyday regimen, and they knew more about the hygiene of the body than we do now. To this alone is ascribed much of their good health and manliness of stature.

TÆNIA SOLIUM.

This woman comes to us with some trouble of the bowels. She speaks of a weak feeling in the upper part of the abdominal region; pain is there in the morning when she gets up; rumbling noises are in the bowels, and there is tympanites. She is never sick in the stomach. The appetite is very good. She eats heartily, but is never satisfied. She could eat every half hour of the day, but is not relieved by eating. We can therefore exclude dyspepsia. She is constipated, and must take cathartics three or four times a week. She has no hemorrhages of any kind. Has a cough; gets hoarse toward evening. Has chills in the morning. Is stout and well nourished, and does not look like a consumptive. She has had this cough for five years, and the probabilities are, therefore, that it is not due to tuberculosis. Altogether this looks like an anomalous case. You will often find an uncertainty and mistiness about the cases that come to you, instead of meeting them clearly defined, as you do in your text-books. Her temperature at this hour, 12.15 P.M., is 99°, and we cannot regard this as high enough to indicate fever. Her cough is dry and irritating in character, and is due either to a dry catarrh of the mucous membrane of the bronchial tubes, or to some reflex cause. A reflex cough is one that is not attended by secretion. There is absolutely nothing in this history to point out the trouble.

There is one thing, however, left in the search for the cause of this abnormal sensation. She has been passing joints of a tape-worm. Has had itching at her anus, and pieces of the worm issue from the bowel when she is not at stool. The symptoms of tape-worm are those of intestinal catarrh, in some cases convulsions and even insanity, which may be cured by the removal of the cause. The only absolute symptom is the appearance of the joints in the stools. There are a number of remedies that are commendable, but more depends on the way the medicine is given than upon the medicine itself. Kousso is recommended. Oil of male fern, ʒ i–ij, will often remove the entire worm. It is well to recollect that it takes as much male fern to kill a tape worm in a child as it does in a grown person, hence the danger in its use in children. Pumpkin seed is one of the best remedies; the poisonous principle lies in the greenish film that surrounds the kernel; the pericarp. The kernel contains an oil, whose properties resemble those of castor oil. After a good saline cathartic let the patient take the husks off the seeds and eat one or two ounces of them at one time. The French method is to grind the hull and all; but as there is no virtue in the hull, except to irritate the bowel, it is better to take it off. I have tried the pomegranate treatment, but it doesn't give good results. Oil of turpentine, ʒ i–ij, is one of the best tænicides, but I am doubtful about using it on account of the kidneys. The French regard the cocoanut as an effectual remedy. In this case I prefer the oleoresin of male fern.

During the next day we will order her to eat nothing but the grated meat of one cocoanut, which is softened by the milk taken from it; then take magnesia sulph., ʒss, at bedtime; and the first thing the next morning let her take:

℞.—Oleoresin. aspidii . . . . . ʒj.
Ætheris sulph. . . . . ʒj.
Fiat mistura, et signa: One-half teaspoonful every fifteen minutes, until all is taken.

Follow this with

℞.—Olei ricini . . . . . ʒss.
Olei tiglii . . . . . ♏ss.
Misce.—Sig. Take at one dose.

When the next passage occurs she should sit over a bucket of hot water, so that the whole worm may pass away without breaking off the head, for if the head remains it will develop again.

INSUFFICIENCIES OF THE OCULAR MUSCLES

AND THEIR TREATMENT WITH PRISMS AND BY GRADUATED TENOTOMIES.

Read before the one hundredth annual meeting of the Delaware State Medical Society at Dover, Delaware, on June 11, 1889.

By READ JENNINGS McKAY, M.D.,
of Wilmington Delaware.

At the annual meeting of this Society last year I was permitted to make some verbal remarks upon a subject which I desire at this time to present to your attention in a short practical paper, viz.: *Insufficiencies of the ocular muscles and their treatment with prisms and by graduated tenotomies.*

Before entering upon my subject, I wish to state very positively and distinctly, that the vision, refraction and accommodation of eyes should receive proper attention before looking for muscular insufficiences.

The method of examination for the detection of these muscular insufficiences which I have followed the past fifteen months, with much satisfaction and success, has been that promulgated so clearly and practically by Dr. George T. Stevens, of New York City, within the past few years. And here and now I desire to state that I consider that Dr. Stevens has given to the profession a method of study and examination of an abstruse and perplexing subject of great utility and importance. I regard it as the natural and necessary sequel of Donder's promulgation of the subject of refraction and accommodation and essentially of secondary importance to the refraction theory.

For the vision of eyes cannot now be thoroughly examined, until their refraction, accommodation and binocular adjustment for distance, are necessarily and consecutively considered.

The examination for insufficiencies is made by causing patients to look through prisms at a fixed light, twenty feet distant (preferably a gas jet turned low to resemble a candle flame,) which will produce diplopia (double sight) laterally or vertically as desired, and observing how the eyes tend in adjustment.

The distance of twenty feet or over is selected, because the accommodation of eyes is considered to be at rest or not used, looking at objects twenty feet distant and over.

Accommodation is the action of the ciliary or accommodative muscles upon the crystalline lenses, and is the procussing of each eye for seeing objects at different distances.

Adjustment is the associated movements of the eyes by the external muscles in binocular vision, and we refer especially to the recti muscles.

These two actions, accommodation and adjustment, are simultaneous and intimately associated, and should be in harmony for comfortable vision, at all distances, *far* as well as *near*.

Whatever disturbs their harmony causes more or less discomfort or suffering, and frequently serious illnesses.

It has been my regular practice for a year past, to test all persons for insufficiencies *before* and *after* I have selected proper glasses to correct their abnormal refraction and before I write the order for their glasses.

It is a great satisfaction after selecting glasses to be able to know that they properly correct not only the refraction, but that the external muscles moving the eyes, perform their functions of making the varied associated movements in binocular vision correctly and comfortably.

Very frequently I detect more or less insufficiency of a simple or complex kind and can usually determine, if not at once, after a second or third visit, whether it needs attention or not, and as soon as possible inform my patient of my decision. If not able to decide the first visit, I loan or order prisms for them to wear for a few days and request them to report again (as recommended by Dr. Stevens); and this continued use of prisms has always afforded me the information desired, by increasing or decreasing the amount of insufficiency at first revealed.

As in hypermetropia (far sightedness), there is but a small amount of muscular weakness manifested at first, and there seems to be a greater amount of it latent, which sooner or later (different in different cases) becomes manifest after using the prisms awhile.

If persons do not suffer pain or some very decided inconvenience from their insufficiencies I do not attempt to correct for them, or in other words I only advise treatment of insufficiencies for persons who actually suffer pain or some disturbing nervous irritation, which, by exclusion of diagnosis, I feel quite certain depends upon the strain caused by muscular insufficiency. This strain affects not only the nerves of the head, but of the spinal cord and its nerves, distributed to the neck, chest, abdomen, and occasionally the lower extremity, which are detailed in the symptoms of the cases I will present in this paper.

All oculists, I presume, have had a similar experience to mine after some years' practice—that of having selected glasses for persons with great care, and yet some of those persons never being able to use the glasses with comfort and satisfaction.

There seemed to be something about such cases annoying to the patient and perplexing to the oculist, and which could not be diagnosticated or relieved.

During the past year I have re-examined quite a number of such patients, and in every instance found that they *all* had some kind of insufficiency.

Some of these cases are related in this paper; others have declined further treatment, and are unrelieved.

During the first four months, after selecting glasses for the correction of refractive troubles, before using the test prisms, I place a dark-red glass (without a prism) before first one eye and then the other, and have the patient look at the light twenty feet distant for a few moments. They frequently manifest double images, which at once indicates (without the diplopia that the first prisms cause) the simple or complex nature of the insufficiency; that is, whether it is insufficiency of the internal, external, superior or inferior recti, or whether there is a complication of the interni or externi with the upper or lower recti. Then the test prisms are used to confirm this observation—which they usually do—and generally more insufficiency is manifested. To determine the amount of deviation from a proper adjustment of the eyes, whether using the red glass alone or with the test prisms, other prisms (such as I show you) are to be held in the examiner's hand before the deviating eye until a prism is found to overcome the deviation, which is to be noted as to the amount and kind of insufficiency found in the case.

The normal standard of power of the various recti muscles to overcome prisms has been estimated by various observers almost unanimously as about 8° abduction, which tests the externi, and from 40° to 50° for adduction, which tests the interni, and about 3° for the inferior or superior recti. Of course, there are many variations from these amounts, consistent with a healthy muscular tone.

I have found that a small amount of insufficiency of the superior or inferior recti (causing a vertical displacement of objects in the effort of adjustment) produces a great deal more discomfort, dizziness, and vertigo than a relatively similar amount of insufficiency of either of the externi or the interni, as mentioned frequently by Dr. Geo. T. Stevens, in his writings upon these subject. Also that the symptoms of the various insufficiencies are very variable in the amount manifested at different times.

In a number of instances I have observed a disappearance of all symptoms of a small amount of insufficiency, after wearing correcting glasses or prisms awhile, and in many others not until a mydriatic was used in addition, to suspend the accommodative powers, did it pass away. This remark refers to cases of insufficiency of the externi or the superior or inferior recti, *but not to the interni.* I have observed convex glasses decrease insufficiencies of the externi, and often correct convergent strabismus of a small amount; but they usually increase insufficiencies of the interni.

Insufficiencies of the interni for the *near point* have for many years been recognized and corrected by prisms, to be used only for the near point of vision, such as in reading, writing, and sewing, and will not receive any further notice in these remarks except that they should always receive attention, and prisms be ordered when needed.

The great importance of these insufficiencies for distant vision becomes manifest when we see the amount of suffering from nervous irritability and general debility, pain in various parts of the body, insomnia, indigestion, nausea, vertigo, spinal irritation, and many other distressing symptoms, which are not relieved by well-directed medical treatment, and *which are more or less promptly relieved when these insufficiencies are recognized and properly treated.*

My object being to give you a few examples of the various kinds of insufficiencies and their treatment, I have selected from my case books the histories of twenty-one cases (some of them have been under observation for years), which I have studied closely and noted more or less fully, and which I believe to be good examples of successfully-treated cases by prisms. They will indicate the various forms of simple and complex insufficiencies, and their satisfactory treatment.

Many of our prominent oculists, I believe, oppose and denounce all operative treatment, and say prisms alone should be used. I have not had the good fortune to see any of the papers presented to the profession by them, demonstrating what they have been doing with prisms. I know there are many cases of high degree of insufficiency which cannot be corrected by prisms that may be worn with comfort, and where operative measures are indicated and prove very successful.

Nor can I fully accept Dr. G. T. Stevens' advice to always operate by graduated tenotomies upon all cases of muscular insufficiencies. I believe he only uses prisms to detect and fully develop the insufficiencies. I understand from his writings, and hear from his friends, his treatment is always operative.

From my limited experience a compromise of the the two methods has given me very satisfactory results, viz., to correct all I can with weak prisms, and to operate by graduated tenotomies upon those whose insufficiencies are too great for prisms. The histories of my cases will give definite information of what I have been able to accomplish. I have also treated many other cases, and have had a large number under observation; but in the pressure of business I have not kept full and complete notes of them —enough, however, to verify and confirm me in the methods of treatment herein advocated, aud which I continue to practice.

Case I.—Miss J. K. M., aged twenty-two, U. S., first consulted me November 1, 1881, for weak and painful eyes. Examination showed far-sightedness and astigmatism. She was ordered +48 glasses for near purposes, and wore these, as desired, until June 1, 1887, when +30 were ordered for all purposes.

On June 14, 1888, she reported that her eyes again troubled her. She occasionally saw double and was dizzy. She did not need a change of glasses, but found to have insufficiency of superior rectus of 1°, with abduction 5°, and adduction 3°. Was advised to wear her glasses constantly; was exercised with prisms twice weekly for some weeks, and given a tonic. She gradually improved; her insufficiency disappeared, and her muscular tone became better. She has continued comfortable in the use of her convex glasses.

Case II.—On April 9, 1888, Mrs. W. M. F., aged thirty-four, U. S. Has not been very strong for years. Her eyes have been weak about two years. Has pain in them, and headache, with dizzy spells. Examination showed far-sightedness and astigmatism. She was found to have a weakness of all of her recti muscles; was examined with prisms, and ordered glasses (+42) to correct her manifest far-sightedness. She wore these three months, when stronger ones were ordered (+30). She was exercised with prisms four or five weeks, and was greatly benefitted.

On April 8, 1889, she reported that she continued very comfortable, and no weakness of recti muscles was found.

Case III.—C. B. R., aged forty-two years, U. S., came to me September 20, 1878, complaining of diplopia. Is a teacher of vocal music in large classes standing in a semi-circle before him. Is accustomed to use his eyes at those times looking to the extreme right and left without moving his head. Is very slightly myopic V. = $\frac{20}{20}$. For some weeks past has had a feeling of fatigue about his eyes, and some days ago double vision began to annoy him. Examination showed homonomous diplopia, due to paresis of right externus, which a 6° prism corrected. He was ordered for R. E. 4° prism base out, and for L. E. 2° prism base out, to be worn for distance constantly. To be used or removed for reading. He wore them for ten years with great comfort for distance.

In January, 1889, he sought advice again, saying his prismatic glasses did not suit him. Examination showed myopic astigmatism.

R. E.—48 cyl. ax 90° V = $\frac{15}{12}$.

L. E.—48 cyl. ax 90° V = $\frac{15}{12}$, and a prism of 2° base out on R. E. to correct insufficiency of his R. externus. These glasses were ordered for distance, and + 24 convex in hook frames to be worn on them for reading. They have given him comfort and satisfaction.

Case IV.—Miss M. E. W., aged eighteen, U. S., was referred to me by a physician for examination of her eyes. She presented herself January 24, 1889. She reported she had chorea four years ago for a time and that her eyes had annoyed her for a year past. She has dizzy spells and a great deal of headache. R. E. V=$\frac{15}{30}$. L. E. V=$\frac{15}{20}$. She has intolerance of light. Ophthalmoscopic examination showed myopic astigmatism, and congestion of the retinæ. Prism test showed insufficiency of external recti of 1°, abduction 6°, adduction 5°. On the twenty-eighth, insufficiency 3°, and inaccommodation 3° to 4°, abduction 6°, adduction 5°, with a 48 cyl. ax 90° each eye V=$\frac{15}{15}$. Wore trial prisms for two weeks and cylindro-prisms were ordered as follows:

R. E.—48 cyl. ax 90°⌒pr. 2°, base out.

L. E.—48 cyl. ax 90°⌒pr. 2°, base out,

which she has continued to wear with great relief and comfort.

CASE V.—On June 5, 1888, Mrs. L. W., aged thirty years, consulted me, stating that at the age of seventeen years, when at school, her eyes began to annoy her and have done so more or less since. Her health is not very good. She has been wearing +30 glasses. Cannot read or sew. Is often kept awake at night by pain in her head and back of neck. Has that pain nearly all the time. She carries her head in a curved, stiff manner as if it were almost immovable. Has tried numerous remedies from different physicians for relief of pain without any perceptible and permanent benefit. Examination showed manifest hypermetropia $\frac{1}{12}$ V=$\frac{15}{15}$, and insufficiency of externi 18° to 20°. She wore the +12 glasses until November, and prisms were tried in the office a number of times. On November 7 insufficiency of externi 20°, abduction 2°, adduction 12° was noted, and a graduated tenotomy of right internus was performed. November 16: Graduated tenotomy of left internus was performed, after which she became very much better. November 25, selected glasses under homatropine, viz.:

R. E.+10^s=+48 cyl. ax 90° V=$\frac{15}{15}$.

L. E.+12^s⌒—60 cyl. ax 180° V=$\frac{15}{15}$. She wore these glasses with prisms bases out, which corrected her insufficiency for a time. Later the insufficiency increased to 12°, and January 21, 1889, a second graduated tenotomy was done on left internus. She is now wearing 3° prisms, base out on each eye, hooked on her sphero-cylinders, and she continued to look and feel better. She will go from a week to ten days with comparative comfort and freedom from pain and dizzy spells. She is worse at her menstrual periods, as she has always been. Yesterday she was reported to have been very comfortable the past month or six weeks.

CASE VI.—On February 28, 1889, W. W. R., a large, strong-looking man, aged forty years, consulted me, reporting that, twelve or fifteen years ago, he began to have pain and strained feelings about his temples and along the sides of his head, extending to post-cervical region of his neck. Has more or less insomnia and indigestion. Has tried medicines ordered by physicians to obtain relief, but none has afforded him any permanent benefit. Attempted to study medicine some years ago, but had to give it up on account of a vague nervousness. If he reads half an hour, his discomforts come on. Has a dull heavy feeling about his head all the time. Worse in the afternoon than in the forenoon. Examination of his eyes showed R. E. V. = $\frac{15}{15}$, L. E. V. = $\frac{15}{12}$; manifest hypermetropia, $\frac{1}{144}$, and insufficiency of the externi 3°, in accommodation 4°, abduction 4°, adduction 5°.

March 1. Insufficiency of the externi 3°. Loaned prisms R. 2°, L. 1°, bases out, to wear constantly.

March 4. Reported he found them very comfortable, and was ordered sphero-prisms

R. E. + 144″ ⌒ prism 2° base out.

L. E. + 144″ ⌒ prism 2° base out.

He began to wear these a few days later, and has reported several times since (the last time June 15) that he is much better in every way. He has gained flesh, sleeps well, little or no indigestion, and no longer constipated. Can attend to his business much more satisfactorily.

CASE VII.—On November 23, 1885, Miss M. H. H., a school girl fifteen years old, first came under observation. For some months past her eyes had annoyed her. During the past week they have blurred and hurt her. The day being dark, R. E. V. = $\frac{15}{20}$, L. E. V. = $\frac{15}{30}$. She was found to be farsighted, and + 36 glasses were ordered for near use. These were used till September 20, 1886, when they were changed to + 30.

October 17, 1887. These were ordered to be worn constantly.

November 22, 1888. Her eyes continuing to annoy her by paining, and their use causing headache, she was found to have insufficiency of accommodation of the interni, in accommodation 10°, abduction 3°, adduction 2°. She also suffered from general debility and sciatica. Electro-vapor baths were taken for the latter. They relieved her promptly, but only temporarily, as near use of her eyes would bring on her severe headaches and sciatica. She was exercised with prisms and loaned a pair of 4° prisms on each side, making a total of 8°, to be used for all near work with her correcting glasses.

November 30. She showed insufficiency of interni 2°, and in accommodation 8°.

December 28. Same. Insufficiency of interni 2°, and in accommodation 8°, abduction 8°, and adduction 8°. She was loaned weak prisms for constant wear (1° on each eye, base in).

January 26, 1889. She was greatly relieved of all of her painful symptoms, and was ordered for distant use,

R + 30″ ⌒ prism 1° base in.

L + 30″ ⌒ prism 2° base in.

To put over them when reading, prisms to correct all the insufficiency for near point, 8°, viz., R. E. prism 3°, L. E. prism 2°.

She has continued to wear these sphero-prisms and prisms since, with much comfort, and pursues her studies satisfactorily. I received my last report from her a few weeks ago.

(To be continued.)

HABITUAL CONSTIPATION IN WOMEN AND ITS EFFECTS.

By SEBASTIAN J. WIMMER, M.A., M.D.

ONE of the most perplexing and obstinate affections that the physician encounters daily is that of habitual constipation in women. It is, however, full of interest, when we consider the many evils emanating from its effects; and becomes doubly so, on account of the relations existing between it and many of the pelvic diseases to which women are so frequently subjected. Nature has established certain laws relative to the well-being of our health, and one of these refers to the proper care of the bowels, regulating them daily, thereby cleansing the system, which readily acquiesces by promoting and stimulat-

ing the various organs onward to the acme of health which enables them to respond to the demands made without unnecessary discomfort or fatigue, thus mollifying the effects of the various maladies which are otherwise apt to confront the individual. This affection, although not a disease *per se*, is a pre-disposing, if not an exciting cause of many of the pelvic and other diseases common to women, for it lightens up maladies pregnant with grave results, when neglected or otherwise uncared for; and too much cannot be said concerning this important subject in order to put physicians on their guard, so as to fully comprehend the importance and bearing of this evil, otherwise the effects of constipation will ever remain obscure and unsatisfactory.

The physiological functions of the human organism are so interdependant, that, where one lacks this influence, others following suit, soon establish a disassociation, which ere long culminates in disease, either, through the general system, or, by a reflex nervous sympathy, thus, encompassing the entire being; for, as is well known, constipation encourages diseases other than merely the local ones, such as hemorrhoids, the various neuralgiæ, etc., it being an important ætiological factor in such complaints as pelvic and uterine congestions, disorders of the digestive apparatus and various other stubborn maladies. Fæcal poisoning at length ensues, affecting the various nervous centers, by its accumulation throughout the organism, sowing the seeds of disease, which sooner or later bear ill-fruit indeed; because the excretions which are retained in the body ferment and undergo decomposition, generating noxious gases, which, with the products of tissue waste are reabsorbed, polluting the blood, and rendering the action of the vital organs sluggish and necessarily incomplete. As stated above, it leads to a mal-nutrition of the nerve centers, which, in turn further renders the system a prey to many disturbances, for an exalted state of the nervous action being evoked thereby, it becomes turbulent and uncontrollable, and we find hysteria, chlorosis and climacteric disturbances of the mind or passions always connected with defective hæmatosis. The liver, secreting less bile promotes uterine congestion; the circulation being slow and imperfect, results follow which cause great distress during ovulation and menstruation, becoming often sources of untold suffering. Chronic constipation frequently causes displacement downward of the ovaries, leading to such complaints as sterility and irritable ovary; and again, the ovaries after becoming displaced are sometimes glued down to their new habitat by inflammatory products of an adhesive character, rendering such cases very often incurable.

Such a condition of chronic torpidity of the bowels not only opens the way to *myriads* of diseases, but actually reinforces the habit of constipation, the patient scarcely giving a thought to her bowels, and the resultant consequences are that the muscular fibers become attenuated, and it then becomes an impossibility almost, when defecation is desired, the large bowel being so inflated by the accumulation of fæcal matter. This state of affairs cannot last long without leaving a trace easily discernible as baneful, the effects of which can be appreciated in the gradual toxæmia that markedly influences the nervous system, by paralyzing its very action, as it were. Every function in the body is depressed—the strength failure, diminished appetite, poisoned condition of the blood, foul tongue, fatigue upon the slightest exertion, headache and unrefreshing sleep, all point to the fact that this condition of chronic overloading of the bowels is fraught with the gravest consequences, calculated to completely undermine the health of the woman.

Hypochondria and mental depression sometimes supervene; some authorities mentioning them as common results of this disorder. The uterus is frequently forced down upon the pelvic floor, and the ovaries made to seek new quarters as we have seen; and this leads us to inquire into the influence constipation exerts in regard to flexions and versions of the uterus. Most writers on gynæcology agree that these various malpositions of the uterus are due, in a part, to habitual constipation. Goodell says; "For, not only are local congestions produced mechanically by the irritation or the pressure from hardened fæces, and flexions of the womb brought about by the straining efforts to empty the bowels; but the intimate interdependence between the pelvic and the uterine plexus of veins on the one hand, and the portal system on the other, is at the root of all manner of female complaints. A congestion in the one determines in the other a like condition, which in turn confirms and augments the disorder of the former. It is, indeed astonishing how quickly a woman's health declines from inattention to habits of regularity."

In anterior displacements of the uterus the means exerted may be entirely mechanical, the primary influence being fæcal accumulation; but, as T. Gaillard Thomas says, in speaking of anteflexions, they may occur from prolonged and habitual constipation, producing likewise flexion of the body, and frequently causing "the cervix to bend sharply forward." He says cervical flexion "is generally produced by pressure directly exerted upon the uterus by tight clothing, which forces it against the concave surface of the vagina. This surface gives the impinging part a slant forward and keeps it thus bent. *Habitual constipation* [italics mine] increases this vicious curve, and the two causes combined often result in an unmanageable form of the affection." Thomas says, in referring to *habitual constipation;* "The habit of allowing large, hard masses of fæcal matter to remain not only for days, but for a week at a time in the rectum, as many women do, contributes largely to the occurrence of this deformity (meaning cervical anteflexion) in the soft, pliable, growing uterus of girlhood. Alone it is sufficient to bend the uterus and give it the shape of a gourd." When this condition is once established. then we may look out for such affections as endometritis, dysmenorrhœa, sterility, etc.; and frequently fæcal impaction causes menorrhagia and metrorrhagia, by producing marked congestion of the pelvic viscera, dependent upon the interference with the portal circulation. Many gynæcologists have attested to these facts, in which fæcal impaction has produced prolonged metrorrhagia, leucorrhœa, and other complaints. The nervous

symptoms due to the constitutional influences of constipation, such as hemicrania, perversion of sight, dimness of vision, the various neuralgias, etc., seem to be due to reflex influences; although they are dependent upon the original cause in the manner previously stated, for we frequently see these complaints and others too numerous to mention relieved when the bowels have been opened. In severe cases of epilepsy occurring in females during their early and middle life, dependent on menstrual disorders, constipation seems to be at the root of the evil, for the bad influence exerted on the general health by it is great. Many, if not all, chronic ovarian troubles are *indebted* (!) to it more or less; one authority having found ninety per cent. of the cases he observed suffering from chronic fæcal impaction. Disturbances of the vaso-motor system are very common. Temperature has been affected, variations occurring quite frequently, some observers having noted typhoid fever symptoms which were well developed; appearance of rash, etc., distinctly discernible. Constipation can cause a relapse in convalescence from low fevers and other typhoid conditions. Ovarian neuralgia, gastralgia, hysterical manifestations, dysuria, frequently result from a loaded colon, sigmoid flexure and rectum. The dysuria is caused by the uterus being pushed forwards, and in rare cases the transverse colon has become so weighted with fæcal matter as to be dragged downwards from its attachments.

Without elaborating on the causes of this unfortunate condition, it may be well to mention that constipation is due more probably to the indifference to the act of defecation than to any other known cause, although a natural delicacy often impels females to avoid the proximity of the closet; but the first-named cause, associated with indolent habits, the prevailing vicious style of dress and an ignorance of hygiene, all combined, are probably the root of the evil. From such habits the bowels gradually are taught to carry a greater and accumulating load, thus causing a loss of activity in the natural muscular movements of the intestines. Prof. Goodell says: "Except as the result of this vicious circle, how else explain the proverbially bad health of women living in the country, and of the poorer classes of women living in cities? Show me such a woman and you show me a costive creature, one whose whole life is spent in an unnatural struggle with the lower but needful calls of her body. This evil is in itself bad enough; but, unfortunately, it does not end there. Upon the good health of the mother depends the good health of the child. Feeble mothers beget feeble children—children who are carried from the womb to the grave, or who peak and pine under the heritage of ill health." Such, then, is the condition of the majority of American women. Such are some of the effects of constipation, and such will always be the case until women learn to regard the laws advanced by *Dame* Nature for her guidance as worthy of respect and practice.

ST. MARY'S, PA.

DR. PHILIPPEAU will hereafter edit the *Gazette de Gynecologie* in place of Dr. P. Ménière, who retires on account of failing health.

Hydrotherapeutics.

BY S. BARUCH, M.D.,
Attending Physician New York Juvenile Asylum and Manhattan General Hospital.

VIII.

DOES not the cold bath increase the tendency to intestinal hemorrhages—is a question I have often been asked—by driving the blood from the periphery to the enfeebled intestinal vessels? Tripier and Bouveret met only four cases among 233 thus treated; of these two died, and none showed any connection with the bath. They conclude that their own experience proves that intestinal hemorrhages are less frequent under hydriatic treatment. Brand, who has studied every phase of this subject with an eye single to the elucidation of the truth, has sifted the histories of hundreds of cases for this purpose. He has gathered 4,995 cases of typhoid fever, in which 155 hemorrhages were noted, 35 dying from the latter. Hence the frequency is 3.1 per cent., and the mortality 0.6 per cent. On the other hand, among 4,890 cases not treated by water, he discovered 271 times hemorrhages, 5.6 per cent., and the mortality from this cause is put down by ten authors whom he mentions as 50 per cent. But Goltdammer, who is not so warm an enthusiast on the efficacy of strict cold baths as Brand, furnishes larger statistics (nearly 20,000 cases), from which he concludes that the cold bath has no influence in producing intestinal hemorrhages. Vogel noted among 251 cases treated by the strict cold bath, only two cases of bloody stools. All evidence, therefore, tends to prove that, so far from being influential in the production of hemorrhage, the cold bath actually renders it less rare and more mild and tractable if resorted to very early in the disease.

"That the alteration in Peyer's glands will not go beyond the stage of infiltration if treatment is instituted before 'the fateful fifth day' is another prediction that raises dubious questionings," says a writer in the *Medical Record*. I reiterate the reply made to this doubting Thomas, because it is a doubt which is but the legitimate offspring of the experience with the expectant treatment hitherto in vogue. Fortunately for the patients, but unfortunately for our pathological enlightenment, the opportunities for autopsy are exceedingly rare in cases treated by the strict cold bath. Only two cases, in which death occurred from other causes, but which had been bathed before the fifth day, furnish evidence on this point. One case is reported in *Lyons Medicale*, No. 14, 1886, and another by Brand in 1883. In the former, dying on the twenty-first day of a typical typhoid, there was no loss of substance, old or new, in the intestine. In the latter (also on the twenty-first day) no ulceration, cicatrix, pigmented spot; only fresh infiltration." If diarrhœa, meteorism, hemorrhage, and a dry, red tongue are indications of ulceration of the intestinal glands, the absence of these symptoms in the large proportion of cases treated by the strict cold bath must be accepted as logical evidence of the absence of ulceration.

Vogl's testimony on this point is strikingly conclu-

sive, and must carry conviction because it emanates from the comparative experience of many years in the same class of patients—soldiers. He says: "The diminution of intestinal symptoms is a very evident effect of the cold bath; a few trials will convince and surprise any one of its success. Among 221 cases there was a daily average of only 0.7 per cent. of diarrhœal stools; while in the cases treated with a combination of baths with medicinal antipyretics, the average was 1.9 per cent. of diarrhœa. Never was it necessary (in 251 cases with carefully written histories) to resort to opium and bismuth; meteorism with tense abdominal walls was observed only in cases received late; it was diminished by the baths. If inappropriate diet is capable, as we know, of aggravating the intestinal symptoms, and if proper diet is capable of preventing or ameliorating them, is it unreasonable to accept the proposition that the ameliorating effect of the cold bath upon the fever process influences favorably the local process, which is but one of the manifestations of the general infection?

Is it practicable to execute the strict cold bath treatment in private practice, especially among the middle and poorer classes? is a question that is frequently asked.

Among the better situated patients the plan may be carried out quite as completely as in a well equipped hospital. I would advise the avoidance of the stationary bath-tub, and indeed I would prefer ablutions to the bath which requires the removal of a patient some distance from his couch for such bath. A compromise might be made by selecting a room connected with the bath-room by a door. This I have done with good results; chiefly, however, in the case of children or persons of light weight.

It is usually not difficult to purchase a large metal or wooden bath-tub. This should be placed so near the bed that the patient may be easily lifted into it or may himself assist in his removal to it. Or one of the portable rubber tubs may be used where space is scant. Among the poorly situated people who cannot be removed to hospital, there can usually be found a large wash-tub, under which some cloths may be laid to prevent wetting the floor. The patient may be held recumbent in the tub, with his feet hanging over the edge, and thus have the larger portion of his body immersed in the water, which may be continually poured over him by the hands and by basins. Imperfect as such a bath may seem, excellent results have been obtained, especially in cases of delirium, coma, or hypostatic congestion. The inconvenience of the method should never debar the patient from its benefits. Brand mentions an interesting illustration of the overcoming of almost insurmountable obstacles by perseverance and confidence in the hydriatic treatment. A child six years old, living in the fourth story of a miserable tenement in Stettin was nursed by its brother of eleven and sister of twelve, the parents being day laborers. The girl also fell sick, and her brother continued the nursing; and when he himself fell ill, he bathed himself in addition. Brand also furnishes the detailed histories of cases of whooping cough, pregnancy, pneumonia, parametritis, heart disease and other affections, which did not prevent the successful execution of the bath treatment.

When the bath cannot be administered, the wet pack may be used with advantage. It consists of a linen sheet wrung out in water at 60 to 65° F. This is laid smoothly upon a blanket; the patient is laid upon it. It is now carefully folded around him, so that no opposing surfaces touch without the intervention of the wet linen. It is snugly tucked around the neck and beyond the feet, while a wet towel is placed upon his head in the shape of a cap. The blanket is now wound over the sheet. The patient lies ten minutes in the pack; another is prepared on the other side of the bed, he is unwrapped and placed upon this. Six such packs will reduce the temperature, as has been shown, several degrees. He is now placed in a half bath; if the latter be not convenient, he is rapidly washed with water not over 60° F., to close the superficial vessels. He may rest three hours, when, if the temperature be above 103° F. the same process may be pursued.

Natural sleep should never be interrupted.

Much tact will be necessary to persuade the patient and his friends to submit to baths. This will prove an almost insurmountable obstacle. But if the attendant has studied the subject by the light of the history and learned the immense change in the chances of recovery wrought by the bath treatment, he will not fail to bring the conviction home to the parties interested. Vogl, who is the most vigorous cold bather and who also keeps his patients in a cold atmosphere, thus expresses himself on this point: As in all other things we physicians cannot always separate our judgment on the utility or injury of any agent (article of diet, etc.) from our own personal observations and sensations, we are likely to gauge the patient's feelings regarding warmth and cold by our own. The noble principle, "Whatsoever thou would'st not have done to thyself, do it not unto others," is the greatest enemy to Brand's method, in the camp of those physicians who like warmth. The unpleasant effect of the shock, and the more or less enduring sensation of cold, which cannot always be avoided, are indeed things to bear in which the patient must be morally supported, but not with the voice of a Mars, as some may suppose, but by persuasion and relation of examples.

The patient's attention should be directed to the life saving import of the bath, and he should be encouraged by reference to those who are convalescing under the same treatment; he sees with joy from day to day in the temperature fall of several tenths of degrees, and in the increasing comfort, the fruition of his resolution, as in the rise of his fevers he observes the need for an increase of the bath. The gentle execution of a severe procedure certainly has an ameliorating effect upon the severity of the subjective sensations. Whoever has noted or is willing to note the undisturbed progress of the bath the whole day and night, in our barracks, must acknowledge that it is governed by as true a spirit of humanity as may be used in any institution. The charge of harshness we can justly deny. This testimony does

as much credit to the heart as his success does to the head of this earnest and painstaking military surgeon, who sinks the officer in the physician. I quote it simply as a guide to those who, though deeply interested in the patient's welfare, may become impatient, if the sufferer wilfully and obstinately interferes with the proper execution of the baths. Moral suasion, gentleness, and a gradual accustoming, as I have pointed out, will surely overcome all prejudices.

In conclusion I may mention one objection to the cold bath treatment, which has been urged by some of my colleagues, and which, though singular, may be shared by many. I refer to an utter disbelief of the correctness of the statistics which have been gathered by the advocates of the cold bath treatment.

Briefly stated, I have shown by carefully gathered statistics ("Transactions of the New York State Medical Society for 1889"), that the cold bath treatment has been instrumental in reducing the mortality of typhoid fever from twenty-one per cent. to one per cent., that the rate of mortality was in direct inverse ratio to the strictness of the bath procedure, and that in 1,200 cases, in which the latter was begun before the fifth day of the disease, and strictly followed, not a single death had occurred.

Such marvellous results are indeed difficult to credit; and I was not surprised to hear a gentleman who has grown gray in the service of suffering humanity, and who is the very highest type of the gentleman and physician, bluntly refuse credence to Brand's statistics. We are prone to be governed by our own personal experience, insignificant though it be in comparison with that of others, because we realize how readily men fall into errors which sustain their preconceived opinions. But it is illogical and unreasonable to refuse credence to statistics which are gathered from several totally different sources, from private and hospital practice in different countries, and among civil and military patients.

Take, for instance, the table of Brand, containing 5,573 cases, treated by the approximately strict cold bathing. *This is gathered from twenty-three different sources*, chiefly hospital practice, in which surely the histories are far more reliable than in private practice The numbers treated by these reporters vary from 11 to 2,711, all the names and other information being given in detail. Brand himself reports 479 cases, from a twenty years' (chiefly private) practice, and, be it understood, there are ten other reporters whose mortality per cent. is lower than his own.

Surely it will not be claimed that twenty-three men, most of whom are hospital surgeons, several of them in charge of large army hospitals, which are necessarily under the strictest supervision by higher officials, have conspired to sustain a false claim, and yet the 5,573 cases reported from these twenty-three sources, give an average mortality of 3.9 per cent.

Whoever studies some of these reports must be convinced by their earnestness, sincerity and genuineness of purpose. Vogl's work furnishes an illustration of the value of his statistics. He has been for many years chief of the military hospitals at Munich. He gives a complete review of all the cases of typhoid fever treated in these hospitals from 1841 to 1881—8,325 cases—*detailing the treatment in vogue each year*. He shows a gradual diminution of mortality from 21 to 2.7 per cent., and concludes, with good reason, derived from these unimpeachable records, "that this is chiefly due to the methodical cold water treatment. A further explanation of these numbers and statements, whose language should not be termed 'enthusiasm,' I deem as unnecessary."

If there exists any statistical therapeutical exposition approaching the above in precision and trustworthiness, I have failed to discover it in the history of medicine, of which I have been a deeply interested student. Individual experience must fall in insignificance before the stately array of statistical evidence, which has been brought forward to demonstrate the eminent superiority of the strict hydriatic treatment over every other in typhoid fever—not alone because of the large numbers involved, but rather by reason of the circumstantial, painstaking, judicial and fair sifting of the evidence furnished by the figures. When the results of surgery under antiseptics were published, skepticism was disarmed by the numerous sources whence they were derived. Aseptic and antiseptic surgery have become the accepted practice of modern times, although demanding great outlay of time, material and funds. The results of hydriatic treatment of typhoid are not less surprising, but, unfortunately, the latter demands so great an outlay of time and trouble that this will ever prove the chief obstacle to its universal adoption. It is my hope to contribute to the latter by this fair presentation of the subject.

ST. LUKE'S HOSPITAL, NEW YORK.

SERVICE OF L. BOLTON BANGS, M.D.

J. V. D. Young, House Surgeon.

SPASMODIC STRICTURE OF URETHRA, DILATING URETHROTOMY.

THIS man gives a unique history. During the past three or four years, he has had at three several times complete retention of urine; these attacks occurring at an interval of about a year and readily relieved by the catheter. History of urethral discharge, simple or specific, is denied. He is married and father of two children. On September 24 last he had another attack, and entered the hospital for treatment.

From the absence of inflammatory changes and the nature of the stricture, which is situated at a depth of four inches and has admitted a sound of twenty-eight F. and from the history of the attack of complete retention, the diagnosis is clear: spasmodic stricture.

The treatment is simple, dilating urethrotomy, cutting the urethra to 30 F., afterwards passing sounds. The meatus in this case is small and we will divide it; the division should always be made slowly and carefully.

STRICTURE OF URETHRA—PERINEAL URETHROTOMY WITHOUT A GUIDE.

The main feature of interest in this case lies in the

fact that it has been subjected to treatment by electrolysis, and under that treatment the stricture became worse. He has had a discharge for eighteen years ever since his attack of gonorrhœa, has close stricture in penile portion of urethra, and two perineal fistulæ; it causes less pain to the patient to urinate through the fistulæ than through the urethra.

The stricture is so closed that it is impossible to pass a staff or filiform guide, so that we will have to operate without this aid, which renders the operation much more difficult. The tissues engorged by chronic inflammatory reaction bleed freely. The urethra is now opened through the bulb. In this operation it is important to keep in the median line. The stricture in the penile portion is exceedingly hard, cartilaginous, and it has always seemed to me that this hardening is due to the use of electricity in these cases.

—K. B. P.

MEDICO-CHIRURGICAL HOSPITAL.

PANCOAST praises the use of the ligature in the treatment of fistula in ano. He uses the black, iron-dyed silk, believing that it has some local action. The ligature is drawn just tight enough to be comfortable, and the patient is allowed to go about his usual business. Every day or two the ligature is "tightened" in this manner: A new cord is tied upon the one already in position, with a tight, small knot. The old ligature is then cut, and serves to pull the new one into position. This process is continued until the fistula is cured. The results are highly gratifying to the patient, no discomfort being experienced.

ESCHSCHOLTZIA CALIFORNICA.—The reported discovery that Eschscholtzia Californica contains an alkaloid apparently identical with morphine, goes to show that there is an ample field for investigation. The *National Druggist* mentioned this fact some months ago, but expressed doubt as to the truth of the statement. In a more recent issue, that journal mentions the investigations of MM. Adrian and Bardet (*Bulletin Générale de Thérapeutique*), who pronounce the alkaloid to be identical with morphine. Besides the alkaloid they have obtained another undescribed base, and indications of a glucoside, which would account for the fact that an extract of the plant produces in cold-blooded animals effects differing from those of morphine, even in large doses. Dr. Ter-Zakariant, who has used an aqueous and alcoholic extract of the plant in the Cochin Hospital, believes that a very valuable sedative and anodyne, free from several of the unpleasant effects of morphine, has been obtained. Dr. W. P. Gibbons, of Alameda, states that Eschscholtzia was described by Chamisso in 1820, since which it has been found over most of the Pacific Coast, Idaho, and other localities west of the Sierras. The original type *E. Californica* includes five varieties, described by different botanists —Douglass, Gray, Brewer, and Watson. Prof. E. C. Green, of the State University, recently informed me that there are five distinct species, and he is authority to be accepted. The plant belongs to the natural order *papaveraceæ*, a name derived from that of the opium plant. Waltz obtained two alkaloids from the entire plant, one of which was a bitter alkaloid, the other an acrid one; he also found a small quantity of chelerythrin, the chemical composition of which is $C_{38}H_{17}NO_8$. I have not seen any more recent analysis, though I have read of late discoveries of other alkaloids. At this day the bare assertion of the discovery of a new remedy, or of an old remedy in a new plant, requires to be sustained by something more than the chemistry of the laboratory before it can be received and endorsed in the medical profession. Years ago I made some experimental tests of the value of Eschscholtzia as a medical agent, without any definite results."

—*Occidental Medical Times.*

GYMNASTIC TREATMENT OF DIABETES.—Dr. Aye records three cases in which this method gave good results. The movements were passive at first; but when it appeared possible for the patient to undertake active movements, these were directed to as many groups of muscles as possible. Along with this there was also carried out the usual dietetic restriction. A man, aged forty-three, fairly nourished, had complained of emaciation for a year, with frequent micturition, much itching, and weakness. Six per cent. of sugar was found in the urine. Under dietetic treatment and opium, the sugar had become reduced to a minimum, but he complained very much of the increasing weakness. Soon after the beginning of the gymnastic treatment, the general condition became much better; the strength increased from week to week in spite of the fact that the patient had given up his dietetic regimen and discontinued the opium; the thirst disappeared; and nocturnal micturition lessened, while the quantity of the urine went down to about two pints daily, the sugar disappearing entirely. (*Berl. klin. Wochensch.*, No. 30, 1889.)—*Practitioner.*

THE ELIMINATION OF LEAD FROM THE ORGANISM BY MASSAGE.—Prof. G. Teneschi reports an interesting case of lead poisoning in which massage caused the elimination of the metallic poison. For two months the patient had been treated with quinine and iodide of potassium, but without any favorable result. During all this time the urine was systematically examined without a trace of the lead being found therein. Massage was therefore commenced according to the indications of Metzger. About two days after the commencement of the treatment the urine gave positive proof of saturnism. The author concludes therefore:

1. Massage cures lead paralysis.
2. As the result of massage, there is a progressive elimination of the lead from the system.
3. Therapeutical action of the massage is established by an increase in the local strength, and by a change in the entire organism.

AUTOMATISM IN MEDICINE.

NOT long ago there was published in Glasgow a collected series of papers and addresses on the Physician as Naturalist, by Dr. William T. Gairdner, in which many strong arguments favoring a broader education and higher mental training for the medical student were advanced. In an admirable address, delivered at the opening of the Medical Department of the Yorkshire College, Leeds, and published in the *British Medical Journal*, the same author presents his views under the head of a plea for thoroughness, and from a somewhat different standpoint.

We have all had our laugh at the "automatic doctor," invented and patented by some ingenious Dutch apothecary. By dropping a nickel in the slot situated where the pain or ailment is located, a pill or two will be shot forth, by the taking of which the patient will be entirely cured. Such an apparatus would be a most convenient consultant, for whether the patient were suffering from colic, neuralgia, hemorrhage, stomach-ache, liver complaint, cough, or rheumatism, he would merely have to drop his nickel and receive the appropriately-labeled drug, without having to be embarrased with questions and examinations. We smile at the novel absurdity of the idea, and yet, both the idea and the smiling are the very essence of sarcasm itself upon a large part of the medical profession. The extent to which automatic diagnosing and prescribing are carried by a large majority of physicians, is doubtless the explanation of the possibility of such a conception as an "automatic drop-a-nickel-in-the-slot doctor." The bitterness of the satire is made even more stinging by the fact of its having originated from an apothecary, who has probably had a large experience in reading the average run of medical prescriptions. So automatic are we becoming, nowadays, that books of brief reference, cramped compends, and countless formularies are literally poured out by the medical presses, and pass through large numbers of editions. Loud is the cry for medical *facts*, and in our colleges and universities there is a set of men who would have nothing taught but facts, just as though there were nothing left still undiscovered and worth studying. The brain-wearied students are compelled to look to mere digests and compends in order to cram their memories with a quota of these innumerable facts. They have no time to stop and think, and hence they have no appreciation of the whys and wherefores of these facts. They graduate, and at once begin practising with facts; and if summoned into the presence of an anomalous case, they will give it a name, and then resurrect from their exhausted memories some appropriate prescription, which they may have heard from the lips of their preceptor or professor.

As the young medical man grows in years, and his practice increases, his hurry to get from one patient to another will not permit him to take time enough to study each case by itself, and so he must needs make rapid diagnoses, usually ordering, at the same time, one of his old favorite automatic prescriptions. Such doctoring gives pith to Voltaire's well-known sarcasm, that the art of medicine consists in putting a number of drugs, of which one knows little, into a body of which one knows even less.

All this begets habits of loose observation and study. Terms are used to describe diseases which mean nothing, or at least are of doubtful utility. Dogmatism and positiveness are palmed off for absolute knowledge, and medicaments are ordered, often upon the strength of one or more prominent symptoms which, in reality, may have nothing to do with the disease itself. Biliousness, myalgia, neurasthenia, irritation of the mucous membrane, are all so charmingly vague that the temptation to diagnose and prescribe for them is well-nigh irresistible. It is so easy to seize upon a symptom or two and call it a disease; it seems so learned to be quick in recognizing a trouble and ordering for its treatment. The evil is common enough in private practice, but alas! what shall we call it as we see it in dispensary work, where twenty or forty patients are run off in an hour? Here automatism has its broadest field for development, and though the temptation to make loose, slovenly diagnoses is great, the danger of the habit once formed is still greater. A dispensary service, like a preceptorship, may be of inestimable value to a student; but it is likewise liable to be a lifelong injury.

The whole tendency of modern life is towards automatism. The struggle for mere existence is becoming sharper day by day. The minute sub-division of labor is rendering us more and more machine-like, with a capacity for doing one thing perfectly, but only one thing. In some respects this is desirable; hence, the tendency in our educational

methods is to narrow down to details and to mould men into mere automata. In science and the mechanical arts, dexterity in minutiæ will always command a higher reward than broad knowledge and general capability. But medicine is more of a liberal art than a science; no one prescription will exactly suit every case of a certain class of disease; no two patients are exactly constituted alike, nor will their systems always respond alike to the same remedy. In educating young men for the profession, therefore, it is the intellect, the powers of observation, and the capacity for reasoning that need to be trained. It is better that the student should see one case only and learn to reason about it for himself, than that he should see a hundred and merely know that it is such a disease and, according to his text-books, requires such a remedy.

A physician whose knowledge amounts to no more than this is in continual danger of committing the grossest blunders. The human brain is not a storeroom, merely into which a mass of facts is to be packed away; it is something capable of the highest volition, and must therefore be trained to will and to act by itself most judiciously. As Dr. T. Clifford Allbutt, a high authority, has said, "A man whose mind has been enlarged and strengthened by a university course will, after a briefer drill, make a more skilful practitioner than one whose technical craft is gained by routine, and is not vitalized by a comprehension of principles." This author has been one of the eminently successful men in medicine, and yet he says that he used to read three books to enlarge his *medical* mind, namely, Grote's *History of Greece*, Gibbon's *Decline and Fall*, and Mill's *Logic*. If we wish, therefore, to avoid turning out automatic doctors from our colleges, we must broaden their education, strengthen their natural powers, and keep clear of the temptation to cram them full of details. We must away with the folly of attempting "to make our education more comprehensive by shutting up our students with individuals, to strengthen their reasoning powers by therapeutical drill, to substitute the ideas of the middle-class parlor for the traditions of a university."

Medicine, like pure art, cannot be practiced by rule; this is the fundamental fallacy of all so-called "schools." It demands the readiest wit, the keenest judgment, the profoundest reasoning, the strongest memory, and the most determined will. Failing any one of these a man is incompletely fitted for the most perfect practice of the art; failing all, he becomes a mere automaton, not made of wood and iron and turned by a crank, but scarcely much more, manifesting the stupidity of a mere vegetable life, and set into motion, as it were, by the formulæ and set facts pumped into him by others. If we would avoid the shame of that travesty upon the medical profession—"the automatic doctor"—we will avoid, in our methods of education, turning out automatic doctors, and becoming such ourselves.—L. H. M.

BLOODLETTING IN CONGESTIVE NEURASTHENIA.

TO the small minority who doubt the reality of such states as cerebral anæmia and hyperæmia, the question of bloodletting in certain forms of nerve exhaustion is an entirely irrelevant one. The old notion that anæmia was the cause of lessened activity, and hyperæmia of increased activity of the nervous elements, was based upon observations occasionally obtained when patients were in a condition of sleep, whose brains were by accident exposed. Experimentation, likewise, seemed to prove that sleep was induced by a diminished amount of blood in the brain, and wakefulness by the reverse. It is now questionable whether this change in the circulation is not, after all, merely a secondary one; whether in sleep the exhausted nerve cells, in falling into inactivity, do not require less nutriment, and so, of themselves, cause a lowering of the circulation. But however this may be, we do know that alterations produced in the circulation by catharsis, and the various measures of depletion in other parts of the body, will affect the activity of the nerve cells. Is not sleep a common sequence of a free venesection in many cases of congestion, and does this not seem to prove that the withdrawal of the blood diminishes the activity of the brain, as well as the fact that its previous excess was the cause of its overactivity?

There is a class of cases commonly met with nowadays among men and women leading confined, anxious, and toilsome lives, associated with mental strain, in which there are many undefinable subjective symptoms, such as a general feeling of distress, lack of interest in things of interest, unsteadiness of purpose, fear of impending physical ruin, low spirits, incapacity to appreciate the pleasures and comforts of life, etc. From these milder symptoms there may be many others of the same character, all the way up to melancholia, on the very borderland of insanity. Occasional faintness, weakened memory, slight incoherency of ideas and speech, irritability of temper, unnatural obstinacy, headache, palpitation of the heart, loss of appetite, unrefreshing sleep accompanied by disagreeable dreams are some of the later signs of this nerve exhaustion indicative of cerebral hyperæmia. But most annoying of all is the insomnia which at times seems absolutely unconquerable by every known hypnotic and remedial measure. The patient will sit in a chair and become almost asleep with drowsiness, but as soon as he lies down in bed there is a kind of thumping wakefulness that no amount of effort will overcome. From loss of sleep the sufferer becomes more irritable and depressed. He is ever longing to get away from his usual surroundings, and when he does, is again disappointed by the little relief he obtains. His appetite leaves him almost entirely. His bowels become irregular to a most troublesome degree. His eyes become now and then blurred. The vertiginous sensations increase. Hallucinations of hearing arise,

and there is continuous tinnitus aurium. The slightest unusual sound is agonizing. The headaches grow more severe—sometimes confine themselves to one side—and become likewise more frequent. Occasionally the severity of the symptoms will be such that friends will notice the change; but more frequently the healthful appearance and glow of countenance common to this class of sufferers, cause them to be deprived of the sympathy they so much deserve. They soon learn to keep reticent about their own wretchedness, knowing that the description of their own horrible sensations will be looked upon as a kind of ridiculous hypochondria. Hence they become morbid and introspective, and so grow to exaggerate their own feelings.

These cases are due to mental strain, and are common enough at the present day. They go about from one physician to another merely to receive tonics, stimulants, and directions to rest and take more exercise; but all to no purpose. Sedatives, hypnotics, blisters, counterirritation, regulated diet, hot foot baths, cold applications, electricity, are all successively tried in vain. The patient is fast sinking into despair, and, as frequently happens, begins to look upon himself as a hopeless physical wreck.

Cases presenting these general symptoms, whatever their immediate cause, hyperæmia or not, will usually respond favorably to blood-letting. Owing to the abuse of this therapeutic measure at one time, it has been allowed to fall into undeserved disrepute. The pendulum of medical opinion sometimes swings far and wide, and while we are crowding our armamentarium with all sorts of new preparations, we are foolishly neglecting some of the older resources that have proved their worth by the test of time. Novelty in treatment is sought after, whereas if a little more attention and judicious thought were devoted to the application of these older methods, far more positive good would be frequently obtained. The hypnotics are admirable in their way, but many of the cases which we have described will respond much more quickly and favorably to the application of a few leeches over each mastoid process, and after the refreshing sleep thus induced, the patient will awake with a clearer head, a brighter spirit, and a much more general feeling of well being. In extreme cases even venesection is called for, but usually the leeches will do quite as well. How simple is this measure, and how surprisingly beneficial at times, in comparison with the overdrugging which is now so common with this class of cases. Usually but a few applications are requisite to institute the change towards improvement, which may then be continued by the careful regulation of the diet, the administration of the appropriate tonics, and the recommendation of travel or some more congenial and restful diversion. We commend to our readers the trial of this treatment; for, whether they believe in congestive neurasthenia or not, symptoms such as those we have rapidly outlined will be surely ameliorated or caused to disappear entirely.

CORONILLA.

THIS is a new heart remedy, an account of which is contained in the September number of the *Therapeutic Gazette*. The plant from which it is obtained, *coronilla scorpioides* belongs to the family Papilionaceæ, and is found extensively in Southern France. According to Cardot, who experimented upon animals, coronilla arrests the heart of the frog in systole. The same author referred in 1886 at Nancy to four cases of cardiac disease in which marked amelioration was produced by this remedy.

Recently Schlagdenhauffen, Gley and Spillman have read papers upon this subject before the French Biological Society. A glucoside named coronillin has been isolated by Schlagdenhauffen and Reef, and administered in doses up to three-quarters of agrain for a man weighing 120 pounds.

The remedy acts particularly upon the myocardium, by increasing its contractility; but it is said that it must be administered in two and three grain doses, or from nine to twenty-two grain doses of the extract to produce its full therapeutic effect.

In seventeen cases, to which Dr. Spillman gave the drug, eight improved, two were slightly ameliorated, and seven remained as before. Diuresis to a slight degree was noted as one of its effects. It furthermore increased the amplitude of the pulse, diminished the œdema, and improved the respiration.

Twenty-four hours is the earliest time that the first effect is noticed after the first dose, and twenty-four hours after the cessation of its use the condition of the patient returns to its original state. Further studies are needed, particularly in view of the varying dosage recommended, and the varied effects obtained of this new remedy.

Annotations.

THE LEHIGH VALLEY MEDICAL ASSOCIATION.

THE Lehigh Valley Medical Association is evidently a live organization; for, not content with the usual annual publication of its transactions, it now comes forth with a monthly periodical—*The Lehigh Valley Medical Magazine*—to be devoted to its own doings. The profession outside of the association's own membership is invited to subscribe for the journal and send news items or other matters of interest. The management declare that they will exercise special supervision over their advertisement pages, to keep them perfectly clear of objectionable matter. We are pleased with the appearance of this first number, dated October, 1889, and will be glad to welcome all succeeding numbers to our exchange-table. The editorial and publishing committee consists of Dr. W. L. Estes, E. M. Green and Charles McIntire, Jr. The office address of the magazine is 104 North Fourth street, Easton, Pa.

TREATMENT OF MORPHINISMUS.

THE treatment of morphinismus by psychical, medicinal, and hydrotherapeutic methods is the subject of a paper by Professor Rosenthal (*Wiener Med. Presse*, Sept. 15). He refers to the value of a psychical influence upon the "sexual sphere." While in the early stages of morphinism the sexual appetite is increased, it sinks later, and the depreciation is manifested by enfeeblement of the erectile power, and not rarely by emission, until the sexual power is entirely extinguished. He has demonstrated this toxic azoospermism in several cases. Rosenthal utilizes these observations in the encouragement of the patients, who usually value their sexual power highly, to persist in the abstinence cure. He substitutes the salts of codeine (chiefly muriate of codeine), given per os, usually in connection with bromide of sodium, forty-five milligrammes, in lieu of one of the usual morphine doses. Codeine produces sleep without disturbing the digestion.

He lays stress upon half baths of 75° F., wet sheets of 75° F.; on tonics and diffuse faradic brushings in gastralgias and diffuse pains. This combined treatment rendered him, in a large number of cases, good service.

A NEW MECHANICAL TREATMENT FOR TABES.

A NEW mechanical treatment of tabes is commended by Juergensen at the recent meeting of the Section for Internal Medicine. In six cases he has observed favorable results from the application of Hessing's corsets, made from finely woven cloth and thin steel ribs. The freeing of the spine produced by wearing the corset soon results in relief from the intestinal and cystic trouble; then the lancinating pains cease, the patient walks better. The patellar reflexes are not restored. The general improvement is most marked. The corset must be worn for years, under the supervision of the maker. No explanation is given by Juergensen, unless the circulation and nutrition of the cord are improved by the extension of the spine.

Erb had seen two favorable cases from the treatment.—*Bul. Klin. Wochenschr*, 30th September.

LONDON POST GRADUATE COURSES.

THE medical staffs of the Brompton Chest Hospital, that for Sick Children, for the Paralyzed and Epileptic, the Royal London Ophthalmic Hospital, and that for Diseases of the Skin, have united in a Post Graduate scheme. Three courses, each of eight weeks' duration, will be given during the year, the first opening on Monday, January 13, 1890; the second on May 5, and the third on October 13. The fee for the first course is ten guineas; that for any one hospital alone, three guineas. A complete prospectus is promised in November.

PHELPS' OPERATION FOR CLUB-FOOT.

A GRATIFYING tribute to American surgery is paid in Büngner's work on the Treatment of Club-foot in Volkmann's Klinik at Halle. Büngner says that Volkmann has given up the division of the tendon of the tibialis posticus as well as other operations, and recommends Phelps' operation as the principal method of operative treatment of club-foot. All the cases of congenital club foot treated by Phelps' method not only recovered without reaction, but have also furnished the most beautiful results with regard to function. We are pleased to note this well merited recognition of Dr. A. M. Phelps, formerly of Chautauqua, now of New York.

Letters to the Editor.

COUNT WALDECK.

SOME time ago I wrote a letter to you respecting the "Brown-Séquard elixir." In it, I asked, "Has Brown-Séquard used his own elixir, or is he another Count Waldeck?"

Believing that some of your readers may not understand why I refer to Count Waldeck I beg to present an extract from *Life in Paris*, by Arsène Houssaye; a series of "Letters on Art, Literature and Society," Boston, 1875; which will explain, and which so far as I know does not appear in medical literature.

PARIS, May 2, 1875.

"People in society in Paris received yesterday the following notice: 'You are requested to assist at the funeral of M. Jean Frederick Maximilian Count Waldeck, officer of the Order of Genius and Merit of Venezuela, honorary member of the London Athenæum, member of the Geographical Society of Archæology, Honorary Vice-President of the Universal Alliance, and author of several works, who has died in his 110th year, furnished with the sacraments of the church at his house, No. 74 Rue des Martyrs'."

Since Count Waldeck, who had been successively page of Marie Antoinette, soldier of the Republic and of the Empire, prisoner of cannibals, ranger in virgin forests, explorer of American ruins, three times shipwrecked, left for dead in a duel, smitten by fevers of all colors—white, yellow, green and blue; married, also, when 83 years of age—since he had neglected so many chances of dying, one cannot help asking how he came at last to die? It was he who invented "the third youth," beginning at sixty years, which we call "St. Martin's Summer." He published a learned book to prove that a man never dies, but commits suicide, whatever his age may be. Count Waldeck, therefore must have killed himself. Death seized him, pencil in hand. On the fatal day, he said that he had ten years of work on hand, and did not wish to lose an hour.

This case was so remarkable that the late Prof. James Aitken Meigs would read the anecdote to his class when lecturing upon generation and sexual vitality.

A. C. W. BEECHER, M.D.

PHILADELPHIA, OCTOBER 14, 1889.

MONO-BROMIDE OF GOLD is recommended by Goubert as the best bromide in epilepsy. It is also useful in hemicrania and in strumous ophthalmia. Medium dose one-eighth to one sixth grain.

—*Merck's Bulletin.*

Society Notes.

ACADEMY OF MEDICINE.

Stated meeting, October 3, 1889.

President LOOMIS in the chair.

A PAPER was read by Dr. C. L. DANA, entitled

A CONTRIBUTION TO THE PATHOLOGICAL ANATOMY OF CHOREA.

W. S., male, single, Swiss, aged eighteen years, was admitted to the hospital December 15, 1888; family history unknown; had always been sickly; emigrated to America at the age of twelve years; the choreic movements came on at the age of eight years.

When admitted to the hospital he was in poor condition, weak and anæmic. There was no heart murmur; urine normal. On the left parietal bone was found a softened spot, where he had been trephined in San Francisco for supposed brain trouble.

Patient's movements were so severe as to prevent his feeding himself, and convulsions of hysterical character occurred, which were treated by chloral hydrate.

December 28. Thirteen days after admission, patient was given physostigmine, under which the movements and hysterical fits improved.

June 6. Symptoms of pneumonia developed.

June 8. Died.

Autopsy.—Rigor mortis fairly well marked; left lung, beginning pneumonia; kidneys small, capsule adherent, parenchymatous changes; other viscera normal. Dura mater not thickened, pia slightly adherent, brain congested; superficial softening found under temporal lobes; no hæmorrhages. Brain and cord placed in Mueller's fluid, afterwards in alcohol. Some of the deeper tissues did not stain or harden well. Microscopic sections made and stained. Slight acute lepto-meningitis. Neuroglia cells not increased, pyramidal cells nearly normal. The chief changes were found just beneath the cortex, and were of a peculiar honeycomb appearance. The spaces and crypts were empty or filled with bloodvessels; the vessel walls were slightly thickened; in the perivascular spaces was an exudate which included blood-cells, and eroded the perivascular spaces as described by Dickinson. Base and top of temporal lobe, superficial edges, showed no trace of degeneration. Basal ganglia did not appear to the naked eye as much involved as the cortex. Internal capsule showed more severe changes in the vessels, something like fatty degeneration and varicosities of the nerve fibers due to increase in myeline sheath, and hyperplasia of the tissue of the neuroglia. Corpora quadrigemina normal. Crura cerebri less vascular than at a higher level. Motor branch fifth nerve apparently normal. A neuro-fibroma, size of a pea, found in the medullary gray matter, floor of fourth ventricle pressed on, but not atrophied. Dura mater of spinal cord normal, pia mater somewhat adherent. No degeneration of anterior or posterior columns. Cerebellum normal. Changes in cord most marked in cervical and dorsal regions; same vascular changes as in brain. Cord had double central canal.

As a summary, we find that the lesions are a lepto-meningitis, degenerative changes in vessel walls, dilatation and erosion of perivascular lymph-spaces, and double central canal.

The mortality of chorea is large in England; three or four per cent. in the English hospitals die. A few years ago the French saw a good deal of the fatal type; the Germans do not report so large a mortality.

The English note particularly changes in the bloodvessels, while the Germans mention those in the connective tissue.

Some 200 cases of acute or chronic chorea have been reported; from these I have selected 39 cases which give a scientific and satisfactory account of the brain lesion. These cases prove the great uniformity with which heart lesions and vascular, perivascular, and nerve changes are found in chorea.

The classification I have adopted and the forms of chorea which I describe are those known as the acute and chronic chorea of Sydenham. Of the 39 cases which I have analyzed, 25 were acute, 14 chronic. Of the 25 acute cases, 6 were of Russian origin; and as I have not had access to the original monograph, I will exclude them, leaving a total of 19 cases. In these cases there was found cerebral congestion and softening, paralysis of the vessel walls (vaso-motor), stasis of blood, thrombosis, disintegration and dilatation of vessels, dilatation of the perivascular spaces by the exudate, neuroglia not increased.

The process is not an inflammatory one, for none of the products of inflammation are found. In the older cases are increased dilatation of the perivascular spaces and the spaces eroded, vascularity increased, and more marked vaso-motor and trophic changes. Changes more marked in the lenticular nucleus and optic thalamus.

The disease was localized earlier in England, and changes looked for in the basal ganglia, often to the exclusion of other parts of the brain. Admitting, then, there are vascular and degenerative changes in the parts mentioned, there were several theories offered as to its etiology: the humeral, embolic, functional, infectious, etc. That there is an abnormal state of the blood is frequently indicated by the fibrinous deposits found on the cardiac valves. As to the inflammation, no changes of inflammatory character are usually found; the small emboli present are not sufficient to account for the lesions. In regard to the infectious theory, the three cases in which micro-organisms were found are not numerically sufficient to warrant its acceptance. My own opinion inclines to a humoral theory, as producing through the blood those changes in the brain which result in the production of the movements known as chorea. These changes are brought about by emotion in a strongly neurotic child, or by a blow or a fall, a kind of traumatic neurosis.

Discussion.—DR. L. C. GRAY: My remarks must be limited to congratulating Dr. Dana on his very interesting and able paper. It is so complete that to add to it would be an impossibility.

Dr. Moses Allen Starr: I join with Dr. Gray in congratulating Dr. Dana. Personally I am inclined to the infectious theory, but agree with Dr. Dana that there are many objections to it. With the relation of chorea to rheumatism, which in one of its forms is known to be infectious, it seems to me that we cannot well afford to throw aside the theory of infection without careful examination. It is a well-known clinical fact that persons with bad blood are more liable to infection.

There have been reported three cases in which micro-organisms have been found, and there is no reason why the lesions which have been so interestingly described may not be due to micro-organisms. This would afford a marked advance in the pathology of the disease.

It is perhaps a difficult thing to determine whether those cases which die and those which live have the same pathology. Many cases must be considered functional, and in these cases we cannot lay down as exact a pathology as in those which die.

Dr. Mary Putnam Jacobi referred to two cases of chorea reported in the last number of *Brain*. In one case, at the autopsy, a peculiar coloration of the brain was found, due to a staining by blood pigment; in this case the most marked changes were found in the cord.

Against the infectious theory was the frequent origin of chorea in mental emotion. A neurotic child fell down a flight of stairs. Chorea developed. Did she catch the infection at the moment of her fall? Dr. Dana's case seemed to imply a congenital cause, as there was a defect in the development of the cord.

Dr. Birdsall: I am pleased to congratulate Dr. Dana, as one of those few who have contributed to the pathology of chorea. While I admit the value of the anatomical lesions, are they the result, or the cause of chorea? Changes, such as have been described, the softening found in the temporal lobe and the congestion of the brain, have also been found in epilepsy. I think they are the result of functional changes. The infection theory is plausible in many cases, but we may have several causes, as emotion, blood infection, etc. An English writer mentioned a pre-choreic state, in which there was a change in the nasal mucous membrane something like diphtheria. Eye strain has also been advanced, and numerous tenotomies have been performed. It has had its brief sway.

At present I am unable to accept the lesions as the cause, not the result. They represent a type, not a distinct disease. As the majority of cases occur in childhood, when coördination is not as perfect as in adult life, when the disease is once established it is easy to see how secondary changes follow.

Dr. Le Fevre mentioned the case of a boy. The mother had rheumatism at twenty years of age, which was followed by a marked protrusion of the eye-balls. A daughter was afflicted in the same manner. The boy, the third son, developed chorea, which was treated for a year. A source of irritation being discovered in a tight prepuce, circumcision was performed. The chorea was relieved. He has since developed the eye trouble.

The President: From a clinical standpoint every one who has a large experience in general practice has noticed the marked connection between chorea and infectious diseases. It occurs largely in families of strong neurotic tendencies, and in a large majority of cases is associated with cardiac phenomena. They have a strong gouty or rheumatic history, as these diseases may occur after the appearance of chorea. I regard chorea as infectious, and that the many so-called causes, emotional disturbances, falls, etc., are merely incident with its apearance, and have no actual relation to the disease. The germ is not caught at the moment of the fall, it is already there. I should be very loath to regard the changes described to-night as the cause of chorea.

Mr. Dana: In replying to the remarks of the President and Dr. Starr on the infectious origin of chorea, I do not dwell on them, as they are so far from being demonstrated; even if the disease was proved to be of germ origin, it would not change the pathology. There is the humoral element of the disease, which may be endogenous, or exogenous. The President's remarks regarding these lesions being found in other diseases, I do not understand. I did not speak of the lesions found as being the primary cause, but certainly they are the result of the microbe or humor, and I believe that the choreic movements are the result of these anatomical changes. The convulsions were hysterical, not purely epileptic, and the brain changes were not similar to those found in epilepsy.

The President: I do not doubt that these changes are found in chorea, but I do not believe that they are found in this disease alone.

Dr. Dana: It is known that we can artificially inject the blood materials which induce these changes, and it does not produce epilepsy, but chorea.

SECTION IN SURGERY.

October 14, 1889.

Dr. Abbe in the Chair.

DEMONSTRATION OF CASES.

Dr. B. F. Curtis presented a man who had received a very deep

TRANSVERSE WOUND OF THE FOREARM,

severing the flexor tendons. They were sutured immediately, but one sloughed; he has fair use of the individual fingers, which but for the sloughing and embedding of the tendons in the cicatrix, would have been much better; the wound was caused by broken glass. Would a second operation in which the tendons were dissected out improve his condition?

Dr. Abbe: I do not see why, if the tendons are dissected out, and allowed to heal in a separate sheath, improvement would not be obtained.

Dr. Sayre: A somewhat similar case was reported by Dr. Phelps, in which the tendons were dissected out, and much improvement gained.

Dr. Phelps: I would like to mention that case again; the man commenced active motion too early, the result was not as good as I anticipated.

DR. GIBNEY: How does Dr. Curtis dress these cases?

DR. CURTIS: The tendons were sutured by the house surgeon at Saint Luke's, and dressed with iodoform.

DR. ABBE presented a case of

REMOVAL OF COMPOUND GANGLION INVOLVING FLEXOR TENDONS OF FOREARM,

ten weeks ago, with perfectly free play of the tendons after operation. In the ganglion were a very large number of melon seed bodies, and a considerable quantity of gelatinous material. These cases are now recognized as tuberculous. Active motion was commenced on the sixth day.

DR. CURTIS mentioned the case of a young girl in whom, as a result of cellulitis, the index finger was bound down by adhesion of the tendon. An incision was made, tendon and sheath formed one mass, a tendon was whittled out, and good result obtained.

DR. PHELPS presented a case of

TUBERCULAR DISEASE OF ASTRAGULUS AND BONES OF THE TARSUS IN A CHILD THREE AND A HALF YEARS OLD.

A first operation was made in which the astragalus and the ends of leg bones were excised; relapse occurring, the bones and sinuses of the tarsus were thoroughly curetted, the whole cancellous tissue of the os calcis being removed; removing the Esmarch bandage, the cavity was filled with blood clot; the wound healed rapidly.

There is total restoration of the os calcis and other bones. After a few weeks the leg was placed in plaster; at the end of thirteen weeks the child was allowed to run around using the leg freely.

DR. POWERS: I would ask Dr. Phelps what histological change took place in the blood clot, by which the os calcis was reproduced? How does the blood clot cause this reproduction of bone?

DR. PHELPS: The blood clot filling the cavities of the bone formed a good basis for the reproduction of the bone; the bone is not developed from the blood clot, but in it.

DR. PHELPS, also presented an Italian woman who at the age of five years had

OSTEOMYELITIS.

The entire femur, tibia, and fibula seemed to be involved, and contraction of the leg on the thigh occurred.

Last November he did an excision on the plan of Fenwick's operation; found a cavity running up to a distance of nearly two inches in the femur; the tibia and fibula were also invaded by a sort of fatty degeneration. The cavity was scraped out, as were also the articular ends of the tibia and fibula, and the bones wired together. Solid bony anchylosis was obtained. The wound healed under one dressing.

The paper of the evening, entitled

KNOTS, LIGATURES AND SUTURES

was read by Dr. B. F. Curtis.

The paper was a thorough review of the various knots, etc., used in surgical practice.—K. B. P.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Abstract of Special Meeting, September 17, 1889.

W. F. KNOX, M.D., President, in the Chair.

BIRTH OF A DEAD AND OF A LIVING FŒTUS.

DR. GREEN reported the delivery of a living and thriving fœtus of about seven months after an easy labor, immediately preceded by the extrusion of a dead fœtus of probably three and a half to four months' gestation. There were two placentæ, one a mass of fat without any trace of vessels, the other normal; each also possessed a separate and distinct sac. This was the second case of the kind he had encountered. In the first the living child was born at term, and the dead one at three or four months.

SYPHILIS COMMUNICATED TO THE MOTHER BY THE FŒTUS.

DR. BATTEN: A patient had syphilis thirteen years ago, and during eight years has presented no sign of the disease. He married, and two years after the birth of a fine, healthy child, presenting no taint, the mother has secondary symptoms. I am positive she was a good, honest woman; and I know the husband has not had syphilis for thirteen years. Was she inoculated through the child, or through the semen of her husband? I believe it was through the child.

DR. GREEN: There is another point in such cases: Some persons who contract syphilis have it violently for a number of years. They have well-marked symptoms periodically. I think that, at such times, they would be perfectly competent to inoculate a woman.

DR. KEARNS: I think it is impossible for the wife to escape tertiary symptoms, and the child will be apt to become affected through her. I believe, with Dr. Batten, that the mother becomes contaminated through the child.

REMARKABLE EMACIATION OF A SYPHILITIC.

DR. WARD reported the case of a man, aged forty-six, who presented complete consolidation of the left lung and syphilis of the brain. His ordinary weight was two hundred and twenty-five pounds, and when he presented himself he weighed one hundred and eighteen pounds. His temperature was 100°, his pulse 90. He expectorated profusely, and anorexia was complete. He improved under the mixed treatment with iron, and is recovering his health and his weight.

DR. BLUME: A married man with several children had primary and secondary syphilis. His wife presented no sign of the disease; her husband had no intercourse with her while he had symptoms. About fourteen months later she aborted: she had no metritis, and her abortion was due to infection. Another patient, who had syphilis twenty-one years ago, presents brain symptoms periodically, and with treatment promptly recovers.

FAILURE OF APPLICATIONS OF MERCURY AND TURPENTINE IN DIPHTHERIA.

DR. KŒNIG: As I reported to this Society some time ago, the success I had had in the treatment of diphtheria by local applications of corrosive sublimate and turpentine, I desire to report the following fatal case. This case was the third in the family, two recovering. The local treatment applied was one grain of corrosive sublimate in one ounce of spirit of turpentine. The application should have been made every three hours, but owing to the restlessness of the patient, it was omitted in the night. The primary seat of the membrane was the nares, and there was also a spot as large as a quarter upon the roof of the mouth. The membrane was black, hemorrhagic, and the child died, despite everything I could do, on the fourth day, from bleeding at the nose.

CHANCROID SIX AND A HALF WEEKS AFTER EXPOSURE.

DR. MCMULLEN: A patient presented himself with a chancroid, which appeared between six and seven weeks after exposure.

DR. STEWART: An unusual case; it was probably a chancre; the time of appearance of the latter may be as late as two months.

Camden Letter.

CAMDEN, as you are aware, is a large and rapidly growing city, and there is much of interest occurring here in medical circles from time to time.

An event of this sort was the regular meeting of the City Medical Society, held on Thursday evening, 10th instant, with the President, Dr. E. L. B. Godfrey, in the chair, and the Secretary, Dr. W. A. Davis, at his desk. The meetings of this Society are held monthly, and are exceedingly interesting. The attendance, as a rule, is large. The exercises consist of the reading and discussion of papers, the exhibition of pathological specimens and the reports of cases of rare or interesting diseases. All of this leads up to the culminating point, which is the banqueting table; around which the members join in social intercourse, and for the time being forget the cares and fatigues of practice. At the last meeting the paper presented for discussion was by Dr. Harry Garratt, entitled "Surgical Shock, its Pathology and Treatment." The limits of this letter will not permit me to give extracts from this valuable contribution, but there were points brought out in the discussion that will, no doubt, interest your readers.

Dr. Dowling Benjamin said that in his experience remedies in shock were often unsatisfactory. It is questionable whether there is any remedy for an impression upon the system so profound as in certain cases of shock. Thinking upon the philosophy of shock, it is problematical whether it is possible to increase the vital force that has been so disorganized by injury. Some scientists think they have proved that the vital force is matter in motion. Vital force is something quite different from chemical force. I hold that it is a distinct force, and does not correlate with the others. Can it be supplied, when absent? Can any drug put vitality into a system profoundly shocked? I have tried it and seen our remedies fail. If a heart is weak and rapid, theory teaches us to give digitalis; and we wait the reaction that may never come. Then what is the matter with theory? Theoretically we may say that digitalis will prove effective, because a certain amount of blood is necessary to relieve shock. But, if we whip up the heart, we increase the liability to hemorrhage. I have watched with much interest the giving of quinine, strychnine, digitalis, etc., and have not been favorably impressed with the results. Ammonia has at times afforded striking benefits, but no one remedy does as much good as alcohol. After alcohol, the secondary shock of the operation is not so great.

Dr. C. W. Henry suggested the use of hypodermic injections of nitro-glycerine, in doses of two minim of a one per cent. solution.

Dr. W. H. Davis thought that in cases of shock attended with profuse hemorrhage, our reliance should be upon readily assimilated nourishment and slight stimulation.

Dr. E. P. Townsend declared that shock is a more frequent accompaniment of railroad injuries than of any other class of wounds. In the army, shock was not so often met with, as men go into battles either with eagerness or laboring under great excitement. Total failure of vital power is death, and shock is an inter-mediate condition.

Dr. O. B. Gross stated that it is said the wisest course to pursue is to desist from the administration of ether during shock. He thought this was a mistake. Ether is salutary in such cases. It acts as a stimulant, and he believes its early use in shock is beneficial.

President E. L. B. Godfrey said: At the last meeting of the Society of Railroad Presidents the question was decided that, after railroad injury, operation should be performed immediately. I am not in accord with those views. In profound shock, let the patient alone so far as operation is concerned. I have never yet known a case of car-wheel injury of the thigh to recover, whether operation was resorted to or not. Thigh cases are fatal because the wound is oblique, and a longer time is required to consummate the injury. The hardest bone and the largest nerve in the body are involved, and the hemorrhage is excessive. The shock is greater than the vitality of the patient, and no remedy is available. Every organ in the body is involved in the perturbating effect. I cannot agree that the stimulating effect of ether is beneficial; the secondary shock of the operation is greater.

Dr. G. T. Robinson related an interesting case of shock occuring during typhoid fever, as the result of profuse loss of blood.

Dr. E. P. Townsend considered it to be a condition of collapse—not shock.

Dr. D. Benjamin said: I have always been desirous of knowing the difference between shock and collapse.

Dr. E. P. Townsend answered that shock is due to failure of vital force; an injury to the nervous system. Collapse is due to loss of blood.

Dr. David Strock called attention to an important indication for the adminstration of the carbonate of ammonium in shock—that is, its power of antagonizing the formation of heart-clot. He thought alcohol stood preëminent among the remedies used in the treatment of the condition under discussion.

Dr. H. Garratt, in closing the discussion, said shock is due to depression of the vaso-sensory system. Treatment should have as its object the arousing of the dormant vital force.

Another event occurring during the past week, of interest to the profession in Camden, was the opening of the Camden Training School for Nurses at the Cooper Hospital. This step was made possible by the courtesy and liberality of the Board of Managers, who have placed the fine lecture room and the various appliances of the institution at the disposal of the members of the medical and surgical staffs. Pupils will hereafter be instructed in all the branches pertaining to nursing in private practice or hospital wards. The course of instruction will be as follows: Medical Nursing, Dr. E. L. B. Godfrey; Surgical Nursing, Dr. D. Benjamin; Obstetrical Nursing, Dr. W. A. Davis; Anatomy and Physiology, Dr. O. B. Gross; Dietetics, Dr. Daniel Strock; Hygiene, Dr. J. H. Wills; Instruction in the Hospital Wards, Dr. H. Genet Taylor and Dr. A. M. Mecray. The inaugural exercises of the school were held on Friday afternoon last, in the presence of a large concourse of prominent men and women of Camden. The Secretary of the Board of Managers of the Training School, Dr. Daniel Strock, formally declared the school opened for the instruction of pupils, after which he introduced the President of the Board of Managers, Dr. H. Genet Taylor, who delivered a most excellent and appropriate address, which was received with applause. The lectures of the course will be delivered every Tuesday and Friday afternoon at 4 o'clock. D. S.

CAMDEN, N. J.

Book Reviews.

WOOD'S MEDICAL AND SURGICAL MONOGRAPHS, Volume III, No. 3, September, 1889, containing Congestive Neurasthenia, or Nerve Depression, by E. G. Whittle, M.D.; The Art of Embalming, by Benjamin Ward Richardson, M.D.; The Etiology, Diagnosis and Treatment of Tuberculosis, by Dr. H. von Ziemssen; Psycho-therapeutics or Treatment by Hypnotism, by Dr. C. Floyd Tuckey; Sexual Activity and the Critical Period in Man and Woman, by Dr. Louis de Sere; Index and Contents for Volume III.

The present number of these excellent monographs is replete with matter that is new and of universal medical interest.

Neurasthenia and nerve depression would seem to be terms of contradiction to apply to states of nerve excitement and exaltation caused by congestion; for the wakefulness, melancholia, lack of fixed purpose, and general fear of impending dissolution so common as symptoms of the conditions herein described, are quite the reverse of those in which there is an actual weakening or depression of the nervous centers. However, the author has here presented a strong argument, based upon actual experience, favoring bloodletting in these congestive states. Nowadays, when nerve section is so entirely neglected as a remedial measure in comparatively mild troubles, the argument seems altogether quite new, and is certainly deserving of the most careful consideration.

Dr. Richardson's brochure on embalming is highly entertaining and particularly practical to those of the profession who care to employ the art for the purpose of making post-mortem examinations, preparing anatomical specimens, or preserving bodies for medico-legal purposes. The ancient and modern history of the art, the method of procedure, and the composition of the preservatives are all fully described and somewhat illustrated.

Tuberculosis, its etiology, diagnosis and treatment, receives practical consideration at the hands of Dr. von Ziemssen. No higher praise is needed in behalf of the authoritative value of his little work than the mere mention of the author's name. Though the disease is not considered in all of its varieties, it is treated in so general a manner as to exhibit its main characteristics and necessary treatment. Despite the general consensus of opinion in regard to the value of Koch's great discovery, the widely different views as to the hereditary character and intimate nature of the tubercular processes renders a carefully prepared resume of this sort extremely valuable and instructive.

Psycho-therapeutics is a timely monograph on the treatment by suggestion. This new addition to our therapeutic resources cannot receive too much study at the hands of the medical profession, if for no other purpose than to deprive quackery of fraudulent profits and criminality a means of doing harm. Hypnotism seems to be a fact, and its proper use is the only question now that remains to be studied. This monograph upon the subject will give a fair idea of what it is, how it may be employed, and the results that may be expected from it. The reports of cases add materially to the force of the general statement advanced.

The final monograph is an essay upon the sexual activity in man and woman. The subject is studied from a physiological standpoint, and though the three chapters comprising the essay do not contain anything that is particularly new, they are exceedingly readable and would highly interest a physician during a leisure hour or so.

Pamphlets.

The Treatment (not Preventive) of Puerperal Fever. By Charles Warrington Earle, M.D., Chicago. Reprint from the Chicago *Medical Journal and Examiner*. 8 pages.

Fortunately this affection is rapidly succumbing to the advances made in obstetric antisepsis. Dr. Earle has given a review of all of the approved methods of treatment, both medical and surgical.

Retained Debris as One of the Causes of Puerperal Fever. The Intra-uterine Douche and Curette. By Charles Warrington Earle, M.D., Chicago. 5 pages.

The heterogenetic origin of puerperal fever is too well recognized to permit of any disregard of antiseptic precautions during parturition, and the author is correct in laying great stress upon the immense responsibility of the obstetrician. He urges immediate operative procedures in every case of high temperature after childbirth.

The Medical Digest.

THE caustic effect of carbolic acid is modified by pure glycerin. If water is added it becomes irritating.—*Apoth. Ztg.*

PUERPERAL IRRIGATIONS (Hebert).—

℞.—Chloral	. . . . .	10 parts.
Borax	. . . . .	5 "
Water	. . . . .	500 "

Tablespoonful for injection with Eguisier apparatus.

—*Gazette de Gynecologie.*

M. MANDOT has induced labor in seven cases attended with eclampsia, obtaining thereby five cures and two deaths. He proceeds thus: he introduces into the cervix, which is sufficiently dilated, a flat metallic canula, breaks the membranes and then injects into the uterine cavity, under very weak pressure, ten litres of a carbolic solution of one per cent. strength.—*Revue de Therapeutique.*

DEFORMED CHEST AND TUBERCULOSIS.—The irregular form of the chest has long been regarded as a factor in predisposition to tuberculosis. But an exact examination of 275 healthy and the same number of phthisical persons, demonstrates that the dimension of the chest walls in the latter is the result and not the cause of the disease. There was no difference found in acquired and inherited phthisis.

—*Deutsche Med. Zeitung.*

EFFECT OF SALT ON DISEASE GERMS.—Dr. J. Forster, Professor of Hygiene at the University of Amsterdam, publishes in the *Tijdschrift voor Genees Kunde* an article on the effect of salt on the germs of contagious diseases. Cholera microbes seemed to be killed in a few hours; whereas typhoid fever germs were found to be still active and capable of communicating the disease after several weeks and even months of immersion in brine.

ANTIPYRIN IN DIABETES has been the subject of several recent contributions by Robin, G. Sée, Dujardin-Beaumetz and others. The remedy is said to be useful in the cases based upon an alteration in the nerve centers; in these cases it does not remove the glycosuria, but diminishes it even while ordinary diet is used. Then a period of rest from strict dieting may be afforded. The dose is 15 grains two or three times a day between meals, continued for eight days, then omitted for a time, especially if albumen appears in the urine. One writter who observed excellent results in the diminution of the urine sugar, rejects the remedy because the digestion is disturbed by it and albuminuria appears. Caution is therefore required.—*Berl. Kl. Wochenschr.*

COLORED SPECTACLES.—Dr. Konigstein, while giving directions to his class on the uses and prescribing of spectacles, said that green glass as a protection against strong rays was worse than useless, and did more harm to a sensitive eye than good, as it allowed the yellow rays to be transmitted and unnecessarily irritated the eye. As a protection against strong rays the blue or smoked glasses were the only real protection. The blue should be light, as a deep blue color produces a violent disc in the centre of the lens, which apparently corresponds to the fovea centralis, and by a protracted use of dark blue spectacles the patient may become annoyed by the mosaic work of the fundus of the eye appearing before him. The phenomenon seems to be connected with the pigmenting changes in the macula lutea.

—*Medical Press and Circular.*

INFANTILE CONVULSIONS (Knagges).—Children under six months should receive every hour a teaspoonful of the following solution:

Sulphate of calcium	. . . . .	0.6 gramme.
Distilled water	. . . . .	250 grammes.

M.

This dose may be increased. In children over one year of age, the dosage may vary from 0.75 gramme to 0.30 gramme every hour. The frequency of administration must depend more or less on the gravity of the case. The medicine should always be freshly prepared, as it becomes rapidly inactive.

—*Revue de Therapeutique.*

TREATMENT OF INGROWING TOE-NAIL.—Dr. Clements strongly recommends the employment of tinfoil in the treatment of ingrowing to-nail. He first has the toe thoroughly washed with soap and carefully dried. He then envelops the whole nail with tinfoil, putting a strip between the portion that grows in and the raw surface caused by it. The tinfoil is fixed by means of a very thin layer of common wax, and the patient told not to wash the part, but to use dry bran for rubbing off the dirt. Of course the toe has to be repeatedly dressed with tinfoil, but, if the operation is carefully performed, it is surprising how long the tinfoil will remain intact; even when the patient is, as as usually the case, very poor and very badly shod. This, he says, brings about in a very few weeks the complete healing of the sore, and causes the nail to grow more slowly, and in a more healthy manner.—*Lancet.*

TREATMENT OF SYPHILITIC VEGETATIONS.—Soft vegetations: M. Zeissl prefers to the alcoholic lotions of corrosive sublimate the use of Pleick's paste, formula as follows:

Corrosive sublimate,
Alum,
Camphor,
Carbonate of lead,
Vinegar of wine, equal parts by weight.

A mixture is thus obtained with which one should bathe the diseased surfaces when the vegetations are of moderate consistency, and until some local œdema or mercurial salivation makes its appearance.

2. Horny vegetations: The same author employs inunctions of a pomade made thus:

Iodide of arsenic	. . . . .	0.60 cent.
Grey ointment	. . . . .	15 gram.

Or better still:

Arsenious acid	. . . . .	0.60 cent.
Grey ointment	. . . . .	15 gram.

Repeat the application two or three times a day by means of a tampon of wadding left in place.

—*Rev. Gen. de Clin. et de Therap.*

PEPSIN POMADE (Douglas).—

Extract of pepsin	3.
Lanoline	10.

To rub upon ulcers and bad appearing cicatrices.

PRIMARY SYPHILIS (Rizat).—

Corrosive sublimate	1 centigramme.
Extract of gentian,	
Chlorate of potash	āā 5 "

In pill. One should be taken night and morning at meal time and continued for three consecutive months.

PILLS FOR PSORIASIS (Bazin):

Oil of Juniper	5 grammes.
Extract of bitter-sweet	5 "
Arsenious acid	0.05 gramme.

M.—One pill, increasing to fifteen or twenty a day.

—*Revue de Therapeutique.*

DIURETIC (Abet):

Mild watery alcoholic extract of chimaphila	10 to 15 grammes.
Syrup of bitter orange peel	25 "
Rum	10 "
Water	80 "

M.—Take tablespoonful every half hour.

ODOROUS PERSPIRATION.—Powder those parts of the body which emit the odor with a piece of lint steeped in the following mixture:

Powdered rice	60 grammes
Subnitrate of bismuth	25 "
Permanganate of potash	10 "
Powdered talc	5 "

—*Revue de Therapeutique.*

TREATMENT FOR TOO ABUNDANT MENSTRUATION (Rheinstadter).—

R.—Dialysed ergotin	10 gram.
Distilled water	70 "
Glycerin	20 "
Salicylic acid	0.2 "

M.—Teaspoonful diluted in three tablespoonfuls of water, to be injected into the rectum once a day after stool.

—*Gazette de Gynecologie.*

NEURALGIA.—A writer in the *Courier Méd.* gives the following as useful in neuralgia:

R.—Alcohol, camphorat	90 parts.
Ætheris	30 "
Tinct. opii	6 "
Chloroform	20 "

M.—Sig. Apply on flannel.

COMBINATION OF COCAINE AND IODOFORM (*Deutsche Medic. Woch.* 1889, No. 24).—In order to prevent the pain which sometimes follows the application of iodoform to wounded surfaces, the following combination may be used:

R.—Very finely powdered iodoform	10 parts
Pure cocaine	0.3 "

Mix carefully and add:

Menthol	0.4 "
French tincture of lavander	20 "

For external use.

—*Gazette de Gynecologie.*

Medical News and Miscellany.

DR. J. MADISON TAYLOR has removed to 1504 Pine Street.

DR. JOHN WELSH CROSKEY, has removed to 3325 Powelton avenue.

DR. ORVILLE HORWITZ succeeds Dr. J. Ewing Mears as demonstrator of surgery in the Jefferson Medical College.

The medical colleges of Baltimore have refused admission to a colored student, on the plea that it would drive away white students, especially those from the Southern States.

THE Linton District Medical Society, one of the oldest in the State will meet at Centralia, Mo., on November 12 and 13, 1889; this will be its eighteenth semi-annual session.

THE cyclorama of "Jerusalem and the Crucifixion," now at the corner of Broad and Cherry streets, will soon be moved to London, England, where it will remain permanently.

WE are informed by Prof. Tyson, of the University of Pennsylvania, that the matter of mixed classes has never been brought before the medical faculty and is not likely to very soon.

DR. LAUDER BRUNTON is about to pay a three months' visit to India, as the guest of the Nizam's Government, for the purpose of testing the results of the Hyderabad Chloroform Commission.

THE celebrated painting of Rembrandt, called the "Anatomical Lesson," has been bought, it is said, by Mr. Ellesworth, for the Institute of Art, of Chicago. It formerly belonged to the Princess de Sagan.

DR. ROSWELL PARK, of Buffalo, has been invited to deliver the Mutter lectures on "Some Point or Points Connected with Surgical Pathology," before the College of Physicians of Philadelphia, during the winter of 1890–91.

THE St. Charles County Medical Society will meet in Warrenton, Mo., on November 19, 1889. This is a live and active county medical society, and will hold its bi-quarterly meeting in Warrington by the invitation of Dr. W. W. Middelbank.

A CHINAMAN, fairly dropping to pieces with leprosy, was recently found in the streets of San Francisco, and sent to the pest-house of that city. He had just arrived from Napa, where he had been employed in picking grapes. N. B.—Don't indulge in Napa Valley wine.

WE are informed that Judge Stinson objected to the classification of the Norristown Asylum patients as white and colored. If this be in the monthly reports only, there is nothing objectionable in it; but if the physicians of that trustee-ridden establishment are going to prevent a race classification of lunatics on the political pretext of "obliterating the color line," they are contributing a very apposite illustration to those who do not believe in that mode of managing an asylum for the insane.

Dr. Charles L. Weed, one of the leading oculists in this city, died October 15, at his father's home, 1804 Green street, of heart disease, after an illness of three months, He graduated from Jefferson College in 1883. Dr. Weed was until his death chief of the eye department of the German Hospital, and had charge of a similar department of the John B. Stetson Dispensary.

Laryngology has lost one of its most prominent representatives in the person of Professor Rudolph Voltolini, of Breslau, who died on September 11, in the seventy-first year of his age. He was born in 1819, and studied medicine at Breslau, and afterwards at Berlin. After spending some years in medical practice, he qualified as *Privat Docent* of Laryngoscopy, Otoscopy, and Rhinoscopy at Breslau, in 1860. In 1868 he was appointed Extraordinary Professor of these subjects, the chair being expressly created for him.

Dr. Philippe Ricord, the celebrated French surgeon, known in Paris for many years as the "great American doctor," is dead. He was born in Baltimore on December 10, 1800.

Dr. Ricord was the grandson of a distinguished physician of Marseilles and the brother of J. B. Ricord, the author of works on language, medicine, and natural history, many of which were first published in this country. Under this brother, Philip made a number of scientific studies and began the study of medicine in this city. In 1820 he went to Paris. In 1828 having begun the practice of medicine at Olivet, near Orleans, he returned to Paris and delivered a course of lectures on Surgery, and in 1831 he was appointed surgeon-in-chief of the Hospital des Veneriens du Midi. At this hospital, from which he retired on account of age in 1860, he gained a great reputation as a specialist. By a decree bearing date July 28, 1862, he was appointed physician-in-ordinary to Prince Napoleon, and on October 26, 1869, was named consulting surgeon to Napoleon III, whom he had assiduously attended during a recent illness, and who in return had presented him with a snuff box and 20,000 francs.

Dr. Ricord became a commander of the Legion of Honor, and in 1871 was made a grand officer for services during the siege of Paris. He also received many foreign decorations. He has been an active writer, several of his works on surgery having been crowned by the Academy of Sciences.—*Press.*

The Guild of St. Luke, Evangelist and Physician.—At the annual meeting of the Guild, held in Philadelphia on St. Luke's day, the following officers were elected: Provost, J. H. Packard, M.D.; Vice-Provost, A. D. Hall, M.D; Warden, Rev. N. F. Robinson; Secretary, T. R. Barker, M.D.; Treasurer, C. H. Burnett, M.D.; Mission Secretary, Rev. C. N. Field; Registrar, Robert P. Robins, M.D.

Council: The Rt. Rev. C. T. Quintard, the Rt. Rev. W. E. McLaren, Blencour E. Fryer, M.D., Dallas Bache, M.D., J. W. Ross, M.D., W. G. Dyas, M.D., Robert Reyburn, M.D., S. C. Chew, M.D., D. R. Brower, M.D.

The revised constitution for the use of the Chapters throughout the United States was presented by the Provost and adopted by the Guild.

The annual report of the work of the Guild was submitted and the special effort directed to the elevation of the standard of religious observances on the part of practitioners and students of medicine, heartily endorsed.

Plans for the carrying on of the good work were matured for the ensuing year.

T. Ridgway Barker,
Sec. Guild of St. Luke.

The Boston *Herald*, while not recommending the use of hair-dyes in general, on the authority of an eminent lady physician, gives two prescriptions which are perfectly harmless. Thus the elixir has another rival in keeping up the appearance of youth.

A Pageant for Charity—A Novel Entertainment Being Prepared by Society Ladies.—The Fair to be given in aid of the Medico-Chirurgical College at the Academy of Music during the week beginning December 16, will be a revelation to society. It will be known as "An ancient and modern pageant, with an annual Leyden Fair." The latter part of the title was suggested by the custom of giving a great annual fair for the sick and the suffering of the Flemish City of Leyden, which was instituted in commemoration of the raising of the siege of the city by the troops of William of Orange in 1574.

The whole lower floor of the Academy, including the stage, will be boarded over, and the decorations and booths will be of a character never before attempted in this city. At the back of the building there will be a representation of a street in ancient Leyden, and the aids will be dressed to represent the inhabitants of a mediæval city of the Netherlands. Around the sides of the building will be erected temples, shrines and houses on an elaborate architectural scale.

Every afternoon and evening that the Fair is in progress, entertainments of various kinds will be given. One day there will be charades, the next tableaux, and the next a theatrical performance. One afternoon the children will have a Mother Goose ball. A thousand young ladies dressed in the picturesque costumes of the times they will be supposed to represent, will act as aids, and on Monday night after the Fair closes they will give a grand ball.

—*Times.*

To Contributors and Correspondents.

All articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Medical Index.

We purpose on this page to give a list each week of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Acute catarrh, the abortive treatment of, of the nose and throat, Bishop. Weekly Med. Review, Oct. 12, 1889.

Abdominal section, Hall. Cin. Lancet-Clinic, Oct. 19, 1889.

Angular curvature, the mechanical remedy, Taylor. N. Y. Med. Journal, Oct. 12, 1889.

Anæmia to chlorosis, the relations of, Forchheimer. Medical News, Oct. 19, 1889.

An unusual healing process, Pettyjohn. The Journal of the National Association of Railway Surgeons, Sept., 1889.

Antiseptic surgery, Stemen. *Ibid.*

Acute and chronic enlargement of the adenoid tissue at the vault of the pharynx, some personal observations respecting, and the means used for their relief, Delavan. N. Y. Med. Journal, Oct. 12, 1889.

Antiseptic solutions, Langdon, Cincinnati Lancet-Clinic, Oct. 12, 1889.

Arthropathies, traitement des, Guyon. Annales d'Orthopédie, 1 Oct., 1889.

Aphorismes sur le diagnostic et la thérapeutique de la tuberculose du larynx, Schnitzler. Revue de Laryngologie, d'Otologie et de Rhinologie, 1 Oct., 1889.

An epidemic of pemphigus neonatorum, E. B. Kilham, M.D. American Journal of Obstetrics, Oct., 1889.

A plea for thoroughness: introductory address by William T. Gairdner, M.D. L.L.D. Brit. Med. Journal, Oct. 5, 1889.

Action physiologique du rein de la salamandre terrestre, par MM. Phisalix et Langlois. La France Med., Sept. 28, 1889.

A study of malarial fever in Eastern Massachusetts, Chas. H. Cook, M.D. Boston Med. and Surg. Journal, Oct. 10, 1889.

Bakterien und Krankheitsgifte. Berliner Klinische Wochenschrift, 30 Sep., 1889.

Backward displacements of the uterus, the surgical treatment of, Strong. Boston Med. and Surg. Journal, Oct. 17, 1889.

Bronchitis, treatment of, Fothergill, N. E. Med. Monthly, Oct., 1889.

Beta-naphthol, further observations upon, Shoemaker. The Therapeutic Gazette, Oct. 15, 1889.

Cæcitis, or appendicitis, Carson. St. Louis Med. and Surg. Journal, Oct, 1889.

Cocillana in diseases of the lungs, clinical notes on, Stewart, The Med. Age, Oct. 10, 1889.

Cocaine, the status of, in surgery, Wyeth. International Journal of Surgery. Oct., 1889.

Curettage de l'uterus, liqueur d'absinthe, vascins ulcereux, vomissements incoercibles de la grossesse. Bulletin par le Dr. Em. Bananlt. Revue de Thérap. Med.-Chir., Oct. 1, 1889.

Climate in relation to disease, D. H. Cullimore, M.D. (Continued.) Medical Press and Circular, Sept. 25, 1889.

Comparaison du bassin de la paralysie atrophique avec le bassin atrophique, à proprement parler, par le Dr. Emile Blanc. Archives de Tocologie.

Case of rhinolith, and two cases of a tooth in the nose, Jonathan Wright, M.D., Brooklyn, N. Y. Medical Record, Oct. 12, 1889.

Case of extra-uterine pregnancy; operation; recovery, L. S. McMurtry, M.D. Amer. Journal of Obstetrics, Oct, 1889.

Combined rectal and intra-uterine irrigator, John S. Coleman, M.D. With woodcut. *Ibid.*

Dyspareunia, caused by a rare injury of the hymen, Paul F. Mundé, M.D. With plate. *Ibid.*

Discussion on removal of bony growths from the external auditory canal. Brit. Med. Journal, Sept. 28, 1889.

De quelques nouveaux diuretiques végétaux, par M. L. Jumon. La France Médicale, Sept. 24, 1889.

Essay on the functions of indifferent cells in the human organism (continued), James Dickinson. London Lancet, Sept. 28, 1889.

Foreign bodies in the eye, C. S. Jeaffreson, M.D. F.R.C.S. London Lancet, Sept. 28, 1889.

Growth of surgery in Europe, William Anderson, F.R.C.S., Medical Press and Circular, Oct. 2, 1889.

Hypnose et suggestions par le Dr. Guermonprez. Revue de Thérap. Med.-Chirurgicale, Oct. 1, 1889.

Heredity, Sir William Turner. Medical Press and Circular, October 2, 1889.

History of protective inoculation, Robert Maguire, M.D. Med. Press and Circular, Oct. 2, 1889.

Inebriety and crime, Prof. R. J. Kincade. Quarterly Journal of Inebriety, Oct., 1889.

Icterus gravidarum, report of a case with remarks. H. Illoway, M.D. Amer. Journal of Obstetrics, Oct., 1889.

Inoculation and vaccination for smallpox amongst the Chinese, James Cantlie, M.B. F.R.C.S., Hong Kong. British Medical Journal, Oct. 5, 1889.

L'hérédite syphilitique, par M. le Pr. Fournier. Feuilleton de la Revue de Thérapeutique Medico-Chirurg., Oct. 1, 1889.

Les recherches récentes sur la tuberculose, par M. L. Greffier. La France Médicale, Oct. 1, 1889.

L'importance pathologique des ligaments larges, par Lawson Tait. Archives de Tocologie, Sept, 1889.

Muscular advancement, F. R. Cross. British Medical Journal, Sept. 28, 1889.

Menstruation et fécondation, par le Dr. Auvard, accoucheur des hopitaux. Archives de Tocologie, Sept., 1889.

Medico-legal problems of inebriety, T. D. Crothers, M.D., Quarterly Journal of Inebriety, Oct., 1889.

Nature and consequences of inebriety, T. L. Wright, M.D. *Ibid.*

Need for a liberal education in medicine: introductory address by T. Clifford Allbut, M.D., etc. British Medical Journal, Oct 5, 1889.

Nux vomica, W. Simonson. Pharmaceutical Era, Oct., 1889.

Notes on leprosy as observed in Antigua, West Indies, John Freeland. Brit. Medical Journal, Oct. 5, 1889.

Nécessité d'un complément à la loi de protection de l'enfance, par le Dr. Jules Rouvier. Archives de Tocologie, Sept. 1889.

Nouvelle methode pour atteindre les organes pelvieux par la voie sacrée, par le Dr. Roux. Gazette de Gynécologie, Oct. 1, 1889.

New antiseptic artificial membrana tympani, John Ward Cousins, M.D. British Med. Journal, Sept. 28, 1889.

On aprosexia, being the inability to fix the attention, and other allied troubles in the cerebral functions caused by nasal disorders, Dr. Guye. *Ibid.*

On some causes of backwardness and stupidity in children, William Hill, B.Sc. M.B. *Ibid.*

On the diagnosis and treatment of scrofulous glands, W. Knight-Treves, F.R.C.S. London Lancet, Sept 28, 1889.

Orifice pubio-périnéal, étude d'anatomie obstetricale, par le Dr. Fallot (suite et fin). Archives de Tocologie, Sept., 1889.

On one form of puerperal eclampsia, Walter T. Colman, M.R.C.S. London Lancet, Sept. 28, 1889.

Perichondritis of the larynx, F. de Havilland Hull, M.D., etc. *Ibid,*

Podophyllum, J. P. Meidenbauer. Pharmac. Era, Oct., 1889.

Review of sixty years in drugs. Pharmac. Era, Oct. 1889.

THE TREATMENT OF CHRONIC NASAL CATARRH.

(Read at the Seventh Annual Meeting of the American Rhinological Association, Chicago, October 10, 1889.)

BY C. F. McGAHAN, M.D.,
CHATTANOOGA, TENN.

CATARRHAL inflammations of the nose and naso-pharynx have been the *bête noir* of specialists, since rhinology has been acknowledged a special branch of science; not that they are hard to cure, but on account of the continuous treatment necessary, and amount of care and prudence that the patient is forced to observe if he wishes to be completely cured. The great Bennett, in speaking of pulmonary phthisis, says: "It is a disease from which no fool recovers." I am sure that these words would be more applicable to chronic catarrh, as there is no disease which takes more perseverance and skill to attend than the one under discussion.

The remedies for the treatment of nasal catarrh comprise almost the whole materia medica. Formerly it was treated principally with strong astringents—for example, strong solutions of nitrate of silver by the post nasal syringe, sprays of tincture chloride, tannic acid, etc. There are some at present who still cling to this form of treatment, combined with Thudichum's nasal douche; but most of us use the astringents but seldom, and then only in weak solutions. It is to Professor Rumbold that we owe thanks for pointing out not only the danger of this douche, but its uselessness. He has shown conclusively that the water from it only bathes the lower and part of the middle turbinated bones, and does not reach the catarrhal secretions, located upon the superior and the upper part of the middle turbinated bones. Therefore, with all due respect to Dr. Seiler, who says in the third edition of his work (which has just appeared) that "if certain instructions are closely observed there will be no unpleasant effects; but on the contrary the patient will be benefited," I must say that I do not agree with him. I can see how the symptoms could be ameliorated for a short time; but from the laws of hydrostatics and the anatomy of the nasal cavity we all know that the douche only does its work incompletely. As science has advanced in the treatment of affections of the mucous membrane located in other parts of the body, we have given up the strong astringents for the bland, unirritating, and soothing applications, and so it is in the treatment of nasal and naso-pharyngeal affections.

Chronic catarrh is caused *first*, by repeated attacks of acute catarrh from frequent colds, the membrane being left more sensitive after each attack; *secondly*, by irritating gases and substances inhaled; *third*, by polypi causing irritation of the mucous membrane around where they are attached. The first, namely cold, is the most common cause, and it produces an hypertrophic condition of the mucous membrane over the turbinate bones and septum.

I will take up the treatment of catarrh with marked hypertrophy and polypi, and then the treatment of the variety with only moderate hypertrophy and no polypi. Where we have polypi, of course, the first thing to do is to remove them, which can be done by the snare or the galvanic cautery, and it depends upon the skill of the operator with these different instruments as to which he will use. For most cases where the polypi are located in the anterior chamber, I prefer the cautery; and Dr. Lewis exhibited a stor-

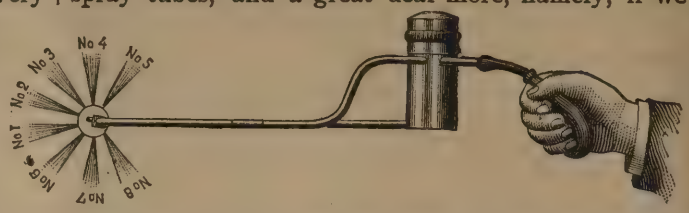
age battery at the meeting of the Mississippi Valley Medical Association that overcomes almost every objection to its use. By this apparatus we can control the amount of heat to which the platinum is raised, the impossibility of doing which has been one of our great objections to this instrument. But when they are in the posterior chamber of the nose, I prefer the snare. The old method of passing a pair of forceps into the nasal cavity, and then—without the eye as a guide—nipping off whatever obstruction came in the way, is too unscientific to receive more than a passing notice.

Having removed all the polypi, the treatment resolves itself into that of ordinary chronic catarrh.

It is of the greatest importance that we impress upon the patient the necessity of frequent visits and perseverance with treatment from the beginning, so that he will not become discouraged. The first point to settle as regards treatment is whether the patient uses tobacco or liquor, and if either, they should be stopped immediately, else what we have gained from one treatment will be counteracted by the vice before the next is given, and after dragging along this way for some time the patient will cease coming, being convinced that he cannot be cured. Where we have hypertrophy of the septum or turbinate bones, the first point to be decided upon is the extent of the hypertrophy.

I am indebted to Dr. G. V. Woolen for a suggestion, namely, if the patient is not able to breathe through the nostrils in the morning it is proof that we should resort to operative measures, which should cease as soon as the patient's nostrils are open in the morning, and then confine our treatment to medicinal and not surgical means. I have not been able to give these suggestions a fair trial, but intend to do so. When marked hypertrophy is present, the best treatment is by the galvanic cautery; you can destroy with it the exact amount of tissue necessary, stopping or continuing its action at will. *Acids* I do not like in the treatment of hypertrophies; it is impossible to control the exact amount of tissue they will destroy; and then the pain is always more intense than after the use of the cautery. The hypertrophy being reduced, we have simply a case of chronic catarrh with moderate hypertrophy, to combat.

In the commencement of the treatment it is always essential that we should spray out the nasal cavity thoroughly, and for this purpose nothing is better than the time-honored Dobell's solution, or the combination with *listerine* which is recommended by Lefert. Seiler's tablets are convenient and effective. In using the spray the stream should be so directed that every part of the nasal cavity shall be reached by it and plenty of solution must be used, the object of it being to remove the mucus from the membrane, so that the medicament can be applied directly to the surface of the membrane. Spraying that will not do this fails in an essential point and cannot be considered to be thoroughly done. I have in my office all the different spray tubes of any value—Sass, Rumbold, Davidson, Richardson, and De Vilbiss, and I must say my preference is for the latter. With it we can do everything that can be done with the other spray tubes, and a great deal more, namely, if we



wish we can douche out the nose. With a De Vilbiss for aqueous fluids, and one of the same make for oils, we are equipped to apply any nebulæ to any part of the nasal cavity.

Having cleansed the nasal cavity thoroughly we are now ready to apply our medicament. When there is moderate hypertrophy I generally use about three times a week a spray of vaseline with a combination of the iodides, or with iodine and carbolic acid. The liquid albolene (as manufactured by McKesson and Robbins) is by far the nicest vehicle that I have yet used, but I find that it does not remain upon the tissues as long as the vaseline, and when we are using it for its protective effects I think that the vaseline will be preferable; but as an unirritating vehicle the albolene is the prettiest preparation. I now use the iodine and iodides dissolved in albolene, first as a spray for their alterative effect, and then spray in pure vaseline alone to protect the tissue from air or any particles that may be suspended in the air. Sometimes I use the chloride of zinc, but in very weak solutions, and very seldom where we have the simple uncomplicated chronic catarrh. After cleansing the nasal cavity thoroughly, I usually spray the parts with vaseline combined with a few drops of eucalyptus or oil of gaultheria, sometimes a drop of carbolic acid to the ounce of vaseline. On account of the hydragogue effect of glycerine upon the tissues it occurred to me some time ago that in hypertrophic conditions of the nasal cavity it might be useful in drawing the water from the tissues and thereby reducing them in size. I had often seen it advised in combination with other drugs in the different sprays, but my way of using it was similar to that of the gynecologists when they apply it on tampons for different hypertrophic conditions of the uterus. After thoroughly cleansing the cavity I apply to the hypertrophic membrane a tampon soaked in a solution of glycerine one part, water four parts, which I allow to remain in from one to four hours.

As the membrane becomes accustomed to the glycerine, I rapidly increase the proportion of it in the solution until I use equal parts of it and water. I advise plugging the anterior nares with absorbent cotton, which prevents the tampon from being expelled. I have been experimenting with this treatment for the past six months, and think it will be found of great benefit in reducing many cases of hypertrophies, and I am sure a trial will well repay you. Dr. Lidlo, at a recent meeting of the Society of Military Surgery in Vienna, advocates a method similar to this for the treatment of ozæna, but he used a spray of 10 per cent. glycerine, which I do not think is necessary; after which he applies a tampon soaked in a solution of glycerine one part, water three parts, which he allows to remain three hours. I must say

I do not advocate insufflations of powders, except it be when the membrane is in a state of hyperæsthesia and then to coat it over with a powder composed of morphine, bismuth, and gum acacia. I consider the constitutional treatment almost as important as the local,—give tonics, and nourishment, try and get the stomach to assimilate food that is put in it, but by all means keep it in a healthy condition. I have had good results from *bovinine* combined with Hoff's malt. Plenty of fresh air and exercise are essential. The most important part of the after treatment is to prevent the patient from catching cold, and once he has caught a fresh cold, to teach him the quickest way to break it.

For the prophylactic treatment the patients must be clothed in flannel, not only over the whole body, but also the extremities; then they must accustom themselves to bathe the head, neck, and shoulders in cold water in the morning, and the feet at night. The cold once caught there are numerous remedies given to abort it. I have had the best results from opium and belladonna, and often add to this a spray of a two per cent. solution of cocaine in the nares. It is of course necessary to give a cathartic. Quinine I do not like as it is not reliable.

As it was my good fortune to take two courses under the late Prof. Elsberg, I would like to give you his directions to abort an acute rhinitis. The first prescription he gave the patient was:

℞.—Ammon. carb . . . . . ℥j.
Liq. morph. sulph . . . . . ℥js.
Mist. amygdalæ . . . . . ℥xij.
S.—℥j every three hours for the first day.

Then when the patient was in bed at night and covered up he gave a diuretic: ℞.—Sp. acetatis ammon. ℥ijss; the next day he gave the morphine mixture every four hours, and the second night a cathartic, as a comp. colocynth pill.

If the cold should return in a day or two take another six doses of the morphine mixture, and then the cathartic; when it seizes the lower portion of the naso-pulmonary mucous membrane take:

℞.—Tr. benzoin comp. . . . . ℥j.
Ext. conii . . . . . gr.x.
Ammon. carb. . . . . ℥js.
S.—Put into a pint of hot water and then inhale the steam. Place mustard plasters over the chest one night and over the back the next.

I simply give Elsberg's treatment to show how we have advanced in our treatment of acute cold in the past few years.

Lotions for Vulvar Pruritus (Percy):

Carbolic acid	1.3	gramme.
Tincture of opium	15	"
Hydrocyanic acid.	7	"
Glycerine	15	"
Distilled water.	120	"

On the other hand Scanlin recommends the following pomade:

Hydrochlorate of cocaine	0.6 gramme.
Lanoline	30 grammes.—M.

INSUFFICIENCIES OF THE OCULAR MUSCLES

AND THEIR TREATMENT WITH PRISMS AND BY GRADUATED TENOTOMIES.

Read before the one hundredth annual meeting of the Delaware State Medical Society at Dover, Delaware, on June 11, 1889.

By READ JENNINGS McKAY, M.D.,
of Wilmington Delaware.

(Concluded from page 627,)

Case VIII.—On October 10, 1888, Mrs. M. E. T., aged forty, first consulted me, saying she had had headache all of her life. Has worn weak convex glasses (selected under a mydriatic) the past six months, with some slight relief. Her eyes ache and blue after near work. Examination shows far-sightedness and astigmatism, and insufficiency of internal recti, from 2° to 3° for distance, and some amount in accommodation, abduction 5°, adduction 4°. She was exercised with prisms daily, and every other day for twelve days, and on October 22 glasses were ordered as follows:

R. E. + 42^{s} ◯ — 144 cyl. axis 15° ◯ prisms 2° base in.

L. E. + 42^{s} ◯ — 144 cyl. axis 165° ◯ prism 2° base in.

This corrected her reaction and insufficiency. She was ordered to wear them constantly, and to report from time to time how she gets along. This she has done, and very favorably (last time May 18, 1888), saying she is free from those headaches she used to have, and when she has pain, it is very slight. She can sew with comfort, and read the papers, but not books, as much as she wishes.

Case IX.—Miss A. T., aged thirty-five, consulted me first October 4, 1882, for scleritis of L. E., which became inflamed seven months previously. She complained of often seeing double. Her eyes improved, relapsed, and improved again, first under salicylate of soda, and later under hydrarg. bichloride, which latter she has used more or less irregularly from time to time for years. R. E. V.=$\frac{16}{70}$. L. E. V. $\frac{16}{40}$ was ordered + 42, as she was far-sighted. March 19, 1883, + 20 was ordered for all distances. R. E. V.=$\frac{16}{100}$, L. E. V.=$\frac{16}{20}$, April 11, + 15 was ordered for near uses.

November 8, 1884, + 12 for near uses was ordered. Declining a mydriatic, as she wanted to continue at work, she was ordered on October 4, 1887:

R. E. + 14^{s} ◯ — 14 cyl. ax. 165° V.=$\frac{15}{30}$.

L. E. + 18^{s} ◯ — 48 cyl. ax. 90° V.=$\frac{15}{12}$. +

September, 12, 1888—She called as requested, and examination showed, insufficiency of interni for distance of 25°. Could not measure it for the near point.

September 28.—Insufficiency 27°.

September 29.—A graduated tenotomy of left externus was done under six per cent. solution of cocaine, until the rectus tendon was entirely cut off, and only 2° to 3° of insufficiency remained.

On October 24, one week later, from 6° to 10° were found, and she would not submit to further operations.

On November 1, 1888, prisms 3° on each side, bases in, were ordered in hook-grab frames to wear on her

distant glasses. These were worn until April 22, 1889, when glasses were ordered under 2 p. c. solution of hydrobromate of homatropine, as follows:

R. E. + 9ˢ ◯ — 8 cyl. ax. 165° ◯ prism 3° base in.

L. E. + 13ˢ ◯ — 30 cyl. ax. 90° ◯ prism 3° base in.

To be worn for all distances. When first obtained and worn on the street she was greatly pleased with her improved vision. She continues very comfortable, but is not able to sew constantly.

CASE X.—Dr. D., aged twenty-four, consulted me first, June 20, 1883, for conjunctivitis palpebral and far-sightedness. October 29, 1883, paralysis of left superior oblique was diagnosticated. He had vertical diplopia, and carried his head to his shoulder habitually. Correcting glasses and prisms were ordered for far-sightedness:

R. E. + 42 ◯ prism 3° base up.

L. E. + 42ˢ ◯ prisms 4° base down.

These he wore with considerable relief to his severe headache. But he did not always wear them, as they often annoyed him. July, 1888, examination of him, after "Stevens' method," detected insufficiency of his superior recti of 26°, and his interni of 70°. Dr. Charles Hermon Thomas, of Philadelphia, saw him with me, confirming the latter diagnosis. The case was transferred to him for treatment. Dr. Thomas has operated upon him five times by graduated tenotomies, three times upon his left superior and twice upon his right inferior recti. The patient has experienced great relief and comfort, and does not have his frequent attacks of most excruciating headache. He wears correcting glasses selected under a mydriatic.

R. E. + 26ˢ ◯ — 60 cyl. ax. 165.

L. E. + 26ˢ ◯ — 60 cyl. ax. 155°;

without any prismatic correction. His insufficiencies have been fully corrected, and he can use his eyes as much as he desires without discomfort.

CASE XI.—On September 28, 1886, M. H. T., aged ten years, a school girl, her father a physician, was brought to me by her mother, who stated that her eyes began to trouble her two years previously by itching, smarting and burning. She had headaches if she used her eyes much. Examination showed far-sightedness, and + 48 glasses were ordered for all uses. On November 20, they were changed to + 30 for all uses. She was somewhat relieved, but her headaches grew worse, and no internal remedy seemed beneficial, as her father reported.

November 22, 1888.—She was again examined. Insufficiency of the superior recti was detected: abduction 4° 5°, adduction 3° to 4°. She was exercised with prism, and wore for some weeks a prism of 1°, base up, on her R. glass, with considerable relief from her headaches.

December 14, 1888.—Homatropine, 2. p. c. solution, was used to suspend her accommodation, and glasses were ordered as follows, to correct the far-sightedness, astigmatism and insufficiency, viz:

R. E. + 18ˢ ◯ — 144 cyl. ax. 180° ◯ prism 1° base up.

L. E. + 18ˢ ◯ — 144 cyl. ax. 180°.

She began at once to wear them with comfort, and has practically gotten rid of her headaches, being very rarely troubled by such pain, and able to attend school regularly.

CASE XII.—September 4, 1888.—Mr. S. J. P., clerk in a grocery store, was referred to me by a physician, to have his eyes examined, as medicines did not afford any relief. He complained of a great deal of headache and dizziness. Has dypsepsia. Examination showed far-sightedness and astigmatism. Insufficiency looked for, but not found; + 36 glasses were ordered, which helped him somewhat for a time.

December 31.—He returned, by the doctor's advice, again. Prism test showed insufficiency of externi for distance, and insufficiency of interni for near point; abduction 6°, adduction 3°. He wore on L. E. prism 1° base down, and out 135° for three days. From January 3 to 20 he wore prism 1° base up on R. E. On January 21 changed 2° prism base up on R. E., and became very comfortable; no pain or dizziness while wearing glasses, but both promptly came on if the prism was removed. Declined use of a mydriatic to correct his refraction, as he could not spare time from his business. February 14, he was ordered;

R. E. + 36ˢ ◯ prism 2° base up.

L. E. + 36.

Which he has continued to wear with comfort, and attend to his business.

CASE XIII.—Mr. F. E. H., aged twenty, clerk and telegraph operator, U. S., was first examined April 19, 1884. He reported his eyes had been weak from time to time for several years after prolonged use. Present attack began twelve days ago. Had to stop work. Not very strong. Ordered hypophosphites comp. V. $=\frac{16}{16}$. Has slight conjunctivitis. Ordered borax and camphor lotion. He was far-sighted and astigmatic, and was ordered + 42 for near uses. July 16, 1884, ordered + 30 for all uses. April 20, 1885, after three days use of a 2 and 4 grain solution of duboisia sulphate was ordered:

R. E. + 18ˢ ◯ — 72 cyl. ax. 180°.

L. E. + 18ˢ ◯ — 72 cyl. ax. 180°, for all purposes. V.$=\frac{18}{12}$.

Continued their use with comfort until April 16, 1888, when he was examined, and found to have insufficiencies of his superior and internal recti, corrected by

R. E. prism 2° base in, and

L. E. prism 1½° base down,

which he was ordered to use in hook-grab frames on his sphero-cylinders for near work. September 18, 1888, he was directed to continue his prisms for near purposes only, as he reported he was very comfortable in using them, although he had 1° of insufficiency of his superior recti, and 1° of his interni for distance, which he declined to have corrected.

CASE XIV.—Dr. M., aged forty-three, in March, 1886, V $=\frac{15}{10}$ +, began to have phlyctenular conjunctivitis of his R. E., and in June, 1886, of his L. E. Both eyes continued inflamed more or less until October, 1886. He was unable to attend to his practice three months of 1886. Began to wear glasses to correct his far-sightedness, and changed them until in March, 1887, he was wearing

R. E. + 30 ⊂ — 72 cyl. ax. 110°.
L. E. + 30 ⊂ — 72 cyl. ax. 40°.
for all uses. Reading and writing continued painful. July, 1887, under a four-grain solution of atropia continued four days, correcting glasses were selected.
R. E. + 24 ⊂ — 60 cyl. ax. 100°.
L. E. + 24 ⊂ — 60 cyl. ax. 50°.
These were worn constantly, and still near use of eyes very painful. Then an additional convex glass in front of his sphero-cylinders was tried (+ 36) to relieve presbyopia. He experienced no perceptible relief from near use of eyes during fall of 1887. In January, 1888, began to look for insufficiency of interni, and it was detected. On March 26 began to use prisms, bases in, R. E. 2°, L. E. 3°, for near uses only, and began to feel some relief. March 31, 1888, began to use sphero-prisms.
R. E. + 36 ⊂ prism 2° base in.
L. E. + 36 ⊂ prism d° base in.
in hook grab frames on his distant glasses for reading and writing. Began to improve slowly but gradually. Later, insufficiencies of superior and internal recti for distance were detected. Was exercised with prisms, abduction 4°, adduction 18°. On June 7, 1888, consulting Dr. Charles H. Thomas, of Philadelphia, he detected that for distance R. E. needed prism of 1° base up and in at 45°, and that L. E. needed prism of 1° base in, to correct distant insufficiencies; and that the above sphero-prisms for near uses were also needed and continued. From that time improvement was steadily progressive, and relief from the almost constant pain on attempting to read was gradually more and more manifest. After one month's vacation during August, 1888, returning home, the insufficiencies were the same for near and distance, viz., R. E. prism 1° base up and in at 45°, L. E. prism 1° base in, and only + 36 glasses without prisms have been worn on distant glasses for near uses.

CASE XV.—Mrs. M. M. H., aged thirty-six, a small and delicate woman, came first under observation November 25, 1887, stating that for sixteen years past she had been weak and sickly. For several years has had severe spells of sick headache, until she began to wear glasses, three months ago. One month ago her eyes began to pain again.

After a week's use of a two and four grain solution of duboisia sulphate, glasses were selected.
R. E. + 24 ⊂ — 72 cyl. ax. 180°.
L. E. + 24 ⊂ — 72 cyl. ax. 180°.
She wore these glasses constantly, but could not read with comfort. She carried her head turned toward her shoulder, could never look up with comfort. Has crossed diplopia, both far and near.

June 27, 1888. Insufficiency of the interni of 2½° to 4° was found; abduction 9°, adduction 6°.

After trying prisms and exercising with them, she was ordered, July 9, 1888:
R. E. + 24 ⊂ — 72 cyl. ax. 180° prism 1½° base in.
L. E. + 24 ⊂ — 72 cyl. ax. 180° prism 2° base in.
These were worn with comfort for a few weeks only; still could not read and complained of diplopia.

September 5 to 20. Insufficiency of interni 7½°, in accommodation 9½°, abduction 6°, adduction 1° to 2°.

October 24. A graduated tenotomy of right externus was done.

November 16. Repeated tenotomy of R. externus.

December 5. Did a graduated tenotomy upon left externus. Her child took sick next day, and she was closely confined, nursing him through scarlet fever, for several weeks. After a number of weeks, insufficiency of superior recti, which had always been looked for, manifested itself, and was corrected by prism 1° base up on R. E. Diplopia still very troublesome, preventing reading. Insufficiency of externi manifested itself (her original trouble being insufficiency of the interni), and she was worse without the prism, which corrected the upward swing of one eye. She wore this prism for some months, and on April 27, 1879, was ordered in her R glass + 24 ⊂ — 72 cyl. ax. 180° prism 1° base up, and continued for left glass + 24 ⊂ — 72 cyl. ax. 180°. Has had very little insufficiency of any kind, and very little diplopia after this time. Her eyes have continued to improve, although she has been very ill with pleuropneumonia this spring.

CASE XVI.—November 13, Miss M. C., aged forty-five, who has charge of a number of children, and sews, stated that in 1875 her eyes began to annoy her. In 1876 a prominent oculist ordered her + 30 glasses. Lately she has been wearing + 20 for all uses with comfort until a few months ago, when they did not suit for near work such as sewing, and + 60 were ordered to wear over them for near uses.

February 19, 1884. + 16 were ordered for distance, and + 12 for near uses.

May 19, 1887. + 20 were ordered in front of her distant ones (the + 16).

On June 6, 1888, she was complaining a great deal, when insufficiency of interni of 1° was detected, and insufficiency of interni in accommodation 5°, with abduction 5°, and adduction 7°. She was exercised with prisms and wore them several days for some hours, and on June 26 was ordered:
R. E. to continue + 16.
L. E. + 16 ⊂ prism 1½° base up and in, at 150°, which she has worn with great comfort ever since.

July 12, 1888. For reading, to correct insufficiency in accommodation, she was ordered;
R + 20 ⊂ prism 2° base in.
L + 20 ⊂ prism 2° base in.
to wear in front of distant ones. In the spring of 1889 one of these prisms was discontinued. She can work much better, but has occasional blurs.

CASE XVII.—Miss E. T., aged sixty-seven, consulted me on July 7, 1888, stating that thirty years ago she had measles, and her eyes had been weak ever since. Twelve years ago she was ordered by a prominent oculist of Philadelphia two pairs of glasses, distant ones and near ones, with prisms, with bases in for insufficiency of interni for near point. She could not wear the distant ones with comfort, but did the near ones for several years. She is a martyr to neuralgic headaches and spinal irritation. Examination detected myopic astigmatism and insufficiency of superior and internal recti, abduction 9° adduction 1°. After a number of trials with prisms, on July 25 glasses were ordered for distance.

R.— 72 cyl. ax. 180° ◯ prism 1° down and in at 135°.
L.— 71 cyl. ax. 180° ◯ prism 4° base in.

To be worn constantly, and for reading wore + 16 in front of them. She could and did wear the distant glasses with more or less comfort, but was not able to read at all satisfactorily.

Returned to me early in March, 1889, and after testing and trying prisms with her reading glasses, she was ordered March 25:

R.+16" ◯ prism 4°, base in.
L.+16" ◯ prism 4°, base in,

which she found quite an improvement, but was still unable to read or sew as much as desired. She was to use them with or without her distance glasses.

CASE XVIII.—Mrs. L., aged fifty-three, consulted me October 17, 1888, saying she had been near-sighted since childhood. Began to wear concave glasses at twenty-four years of age. Now is wearing No. 5 concave and V=$\frac{15}{30}$, but cannot read at all lately with or without them. She is suffering very much from bad sick headaches. Being in a moving crowd distresses her very much. Examination showed compound myopic astigmatism, insufficiencies of superior 5°, and internal recti 2°. Prisms to correct this were loaned her, which she wore for several weeks with her concave glasses, when the following glasses were ordered:

R.—5½" ◯—60 cyl. ax. 180° ◯ prisms 3°, base in.
L.—5½" ◯—60 cyl. ax. 186° ◯ prisms 5°, base up,

which she began to wear at once. After several days she became used to them, and wears them for distance with great comfort and satisfaction. For reading and music she puts on them +16" in hook grab frames, and gets along fairly well. A few weeks ago she confirmed this report.

CASE XIX.—On January 9, 1889, I examined A. G. S., a school-girl aged sixteen years (daughter of a physician) who was reported as always having had headaches and they were worse lately. No medical treatment seemed to help her. She was nervous and irascible to an unusual degree. She is not strong. Her vision was $\frac{15}{12}$. Has slight far-sightedness, and insufficiencies of her superior and internal recti. She was loaned, R. E. 3°, base in.

L. E. 4°, base up.

which she wore with comfort from the beginning. Removing them created immediate confusion and dizziness, and she desired them put on. She only wore them irregularly although requested to wear them constantly, but she would not, out doors, for some time. Her headaches and irascibility soon greatly improved after she had worn them constantly awhile. On February 2, 1889, was ordered:

R. E. prism 6°, base in.

L. E. prism 4°, base up, in eye-glasses. She wore these constantly for several months, with great relief of all of her painful symptoms. I met her June 20, and she reported herself very comfortable and *unable to do without her prismatic glasses.*

CASE XX.—On November 6, 1888, Miss E. C., aged twenty-seven, U. S., called to see me about her eyes, reporting they had been weak and painful two or three years. She has had a great deal of neuralgia on left side, and her left eye has been misty at times. Examination showed considerable myopia without glasses, which she had never worn.

R. E. V=$\frac{15}{70}$ and increased to $\frac{15}{30}$ by —9" glass.
L. E. V=$\frac{15}{200}$ and increased to $\frac{15}{30}$ by —4" glass.

Further examination by prism test showed insufficiency of superior and the external recti. She tried plain myopic glasses,

R.—10,
L.—4,

for a time, returned them, complaining she could not wear them. She was tried a number of times in office with prisms, and on November 22 was ordered:

R. E.—10" ◯ prisms 3°, base up.
L. E.—4" ◯ prisms 5°, base out.

These she could not wear. They made her dizzy and afraid of falling. She is now wearing near-sighted glasses without prisms.

CASE XXI.—On March 29, 1889, Wm. G. R, boiler maker, aged thirty-one, had his left eye injured by a flying chip of iron, which caused a vertical rupture of cornea and sclerotic at the outer margin of cornea, and prolapse of a portion of iris, with intra-ocular hemorrhage. The prolapsed iris was snipped off under cocaine, and compressed bandages worn constantly. V=$\frac{15}{200}$. Local treatment was kept up (cocaine and atropia) securing and keeping up dilatation of pupil. During next ten days a number of paracenteses were done. His eye improved very satisfactorily, and about April 15, he wished to try to work. V=$\frac{15}{40}$. When he looked with both eyes he had diplopia, which was painful and very annoying to him. Examination with prisms showed it to be insufficiency of superior and external recti. He was loaned prisms on April 18, for his insufficiencies:

R. E. prisms 4°, base out.
L. E. prism 2°, base down,

which blended images promptly and with comfort. He went to work with them, and reported on 25th the prisms continued comfortable, and prisms removal caused confusion, pain and dizziness. To continue their use. On May 2, reported not so comfortable, eye painful. Examination showed a change in the disappearance of the insufficiency of the superior recti, and a slight increase of the insufficiency of external recti from 4° to 5°. Prisms were given: R. E. 3°, base out, L. E. 2°, base out.

March 27, the insufficiency of externi was 7° and prisms were given him:

R. E. 4°.
L. E. 3°, bases out, which he is still wearing with comfort.

A brief resumé of these twenty-one cases shows two cases, I and II, were slight insufficiencies relieved by wearing correcting glasses, and being exercised with prisms for a few weeks, and taking internal remedies to improve their general health.

Cases III, IV and VI are insufficiency of the external recti relieved by correcting glasses and prisms, but case V with a large amount of insufficiency externi (18° to 20°) required three graduated tenotomies and prisms as well as correcting glasses.

Cases VII and VIII were insufficiency of the interni and relieved by correcting glasses and prisms, but case IX with 27° of insufficiency of the interni

for distance, had a tenotomy done correcting about 20°. Declining further operations, sphero-cylindrical prisms were ordered.

Case X insufficiency of the superior recti of 27° was relieved by five graduated tenotomies by Dr. Charles H. Thomas, of Philadelphia, Pa., and correcting glasses without prisms.

Cases XI and XII, also insufficiency of the superior recti, were relieved by glasses and prisms.

Cases XIII, XIV, XVI, XVII, XVIII and XIX insufficiencies of the superior and internal recti were relieved by correcting glasses and prisms.

Case XV also insufficiencies of the superior and internal recti was not relieved by correcting glasses and prisms, until three graduated tenotomies were done.

Case XX, insufficiencies of superior and external recti was not relieved by correcting glasses and prisms and declined tenotomies.

Case XXI, traumatic in origin, insufficiencies of the superior and external recti were relieved by prisms alone, the insufficiency of the superior recti disappearing.

THE PROPER USE OF ERGOT IN LABOR.

Read before the Syracuse Medical Association, Oct. 8, 1889.

By F. O. DONOGHUE, M.D.,

Member of Medical Staff of St. Joseph's Hospital.

THAT there should be any diversity of opinion concerning the use of a drug so frequently brought into requisition in the lying-in room as ergot is somewhat surprising, considering that its physiological properties are so well understood. The specific action of ergot is to produce contractions of the uterus and to lessen the intervals between each pain. The explanation of this unquestionable action is the stimulation of the center for the uterus in the spinal cord, or that the drug acts directly or indirectly upon the muscular fiber through the blood supply. Be this as it may, there is no disagreement among medical men as to the statement that, when administered in ordinary doses, it is pretty certain to produce in the parturient uterus powerful and persistent contractions. Notwithstanding this universal agreement as to its action, ergot is given in labor by different physicians in widely different conditions. Some give it to stimulate the uterus in all stages of labor; some to expel a retained placenta; some advise it in uterine inertia from any cause whatever, and others administer it as a prophylactic against post-partum hemorrhage; still another class give it merely as a matter of routine.

In my own practice I find myself giving less and less of ergot yearly; in fact I might almost say I have ceased giving it. I have learned that in most cases the pains are better adapted to their purpose than any modification we may make, and in case there be any disproportion between the size of the fœtus and the pelvis of the mother, or any obstruction to delivery, I believe a prompt application of the forceps is preferable. The physician is then master of the situation. He may exert little or much force, as is required. It is well known that, if a dose of ergot be given, this may be followed by tetanic contractions over which we can exert no control. It is also well known that these contractions are very destructive to fœtal life, as in the intervals of normal labor-pains ăeration of the fœtal blood takes place in the placental capillaries. Ergot, therefore, interferes seriously with the fœtal circulation. If speedy and rapid delivery do not take place, the death of the fœtus is likely to ensue. Moreover, the lacerations of the uterus and perineum which may follow the administration of ergot should not be forgotten.

Upon what grounds ergot is administered for the expulsion of the retained placenta I cannot conceive, It produces exactly the opposite condition hoped for: of firm contraction, and holding in a vice-like grip the secundines which we are endeavoring to deliver.

As a prophylactic against post-partum hemorrhage, other means more speedy and certain in action should be invoked, Those who depend upon ergot for its control are pretty sure to be sadly disappointed. We have no warning that post-partum hemorrhage is about to take place, and it is certainly not justifiable to administer it in every case, anticipating it.

I am impressed with the belief that we would hear less of retained placentæ, hour-glass contractions, uterine and perineal lacerations, and stillborn children if ergot were less freely given than it is at present.

The question might be very appropriately asked, Under what conditions could ergot be given with benefit. The answer: When, from any cause, there is uterine inertia, and there is no possible obstruction to immediate delivery. Then ergot may be given.

I am not an extremist to desire that ergot be expunged from the obstetrician's aid. Nor do I wish to inveigh against it as an invaluable remedy in some conditions. Yet I desire to enter an emphatic protest against its use as a matter of routine in obstetric practice. The cases must be very rare indeed which call for its administration.

PATHOLOGY OF SEVERE BURNS.—Dr. Oscar Silbermann, of Breslau, studying the clinical and pathological signs of the destruction of numerous red-blood corpuscles, found by his experiments: 1. That after extensive burns of the skin the red blood-corpuscles alter their form and lose their power of resistance to heat, drying, compression, and staining. 2. In consequence of these alterations numerous thromboses in the arterioles and capillaries, especially in the finer branches of the pulmonary artery, occur, leading to stasis in different organs—*e. g.*, lungs, kidneys, stomach, bowels, liver, spleen, skin, and brain. 3. The large deviation of the pulmonary capillary circulation produces a considerable impediment to the emptying of the right heart and serious venous congestion, as well as dangerous arterial anæmia. 4. This state, coupled with the above-mentioned symptoms, leads to bleeding and parenchymatous alterations in the affected organs. 5. The interference with the circulation also produces dyspnœa, a small pulse, angina, eclampsia, and anuria, as well as a remarkably low temperature.

ABSINTHE.

A PHYSIOLOGICAL study of absinthe made by Messrs. Cadeac and Meunier, a few weeks ago, seemed to prove that absinthe itself was not dangerous. These gentlemen found that the liquor sold under that name did not contain absinthe alone, but consisted of a mixture of absinthe, anise, badian (or the star anise), coriander seeds, fennel, mint, and some other less harmful aromatics. Taking each substance separately and giving it to animals, they decided that the absinthe was relatively innocent, while aniseseed was the most dangerous part of the drink. A new study of the matter, however, by Dr. Laborde, the distinguished chief of the physiological laboratory at the Faculty of Medicine in Paris, proves that the first experimenters were in error. Dr. Laborde found, on injecting a cubic centimetre of essence of absinthe (that is to say one gramme) into the cellular tissue of a guinea pig, that the animal was taken at once with a violent convulsive attack, with all the symptoms of epilepsy, which gave it no rest until it expired about an hour afterwards. On making the same experiment with ess. anise on another animal, not the slightest symptoms of convulsion followed. These series of careful experiments only confirm the already accepted opinion, that absinthe has a most dangerous influence over the human organism, when injected, and that it is not true that the aniseseed, and other aromatics used in its preparation, have much influence over its toxic action.

CARBOLIZED SOLUTIONS.

A rather important fact has been brought out by M. Carles. It is to the effect that carbolic acid solutions differ according to what is used for dissolving the acid. One of the most interesting solutions is with glycerine; here it was found that no matter what the degree of concentration, the solution *was not caustic*, and that it is well supported by the mucous membranes, while solutions made with water will burn even the unbroken skin, not to speak of the caustic action of such solutions on the mucous membranes, which all know to be extremely caustic. Even the glycerine and alcoholic solutions become caustic when the slightest quantity of water is added. The outcome is not to use any water in such solutions when intended for internal, or even local, use.

ASTIGMATISM.

The late congress of the *Société Française d' Opthalmologie* had an excellent meeting, and one of the most interesting papers was one giving some observations tending to show that "regular astigmatism, unassociated with disease of the cornea, is subject to variation with age." This subject was treated in a most original manner by Dr. George J. Bull, of Paris, formerly of America and Canada.

Dr. Bull gave the results of a study of a large number of cases that had been examined by Dr. Javal for the last twenty years, and also of a considerable number that had been carefully gone over by Dr. Bull himself. The whole number of cases was grouped in methodical tables, and the difference was noted as they were observed at the several examinations made; and they were then compared with one another. Although considerable differences were several times observed, Dr. Bull did not feel justified in concluding that astigmatism may increase or diminish with age. But a case, absolutely characteristic, observed with special care by the subjective method, and studied with the ophthalmometer, having shown him an increase of two dioptrics in the corneal, and total astigmatism of a young subject, he then believed that however rare such variations may be, and however difficult to explain in the present state of the etiology of the subject, we must, however admit that they do occur. The practical conclusion follows—that we cannot rest satisfied with one determination of a patient's astigmatism, but we must re-examine his eyes from time to time.

CEREBRAL WOUNDS.

The delicate question of cerebral and medullary traumatisms, and their relation to legal medicine, was brought up in The International Congress on Legal Medicine, and, after a very complete discussion by all the leading lights present, it was decided that "In the present state of science it is difficult, if not impossible, for a physician to determine exactly the consequences of such injuries, as patients who seemed to be seriously injured have been known to get well after a few weeks or months; and others who do not seem to be much affected by the accident will yet suddenly be taken with most serious symptoms, even after a long time, and they then fail to return to health. So that, only by a *very long* and attentive observation of such cases can a proper prognosis be made out." Under these conditions, doctors should not be held to give an absolute appreciation of the actual state or of the future cure of such patients. A definite opinion can only then be given after a lapse of considerable time. The court can, in the meanwhile, give some temporary relief as may be thought just, until the final report can be made that can establish the extent of the injury. This is interesting to all physicians who may be called to testify in accident cases.

WHOLESALE SALES TO OPIUM-EATERS.

Drs. Luteaud and Decoust, in the same Congress, called attention to the fact that the morphinomaniacs have taken to buying their drug from wholesale druggists, either directly or through some friend or messenger. The only restriction put upon wholesale chemists has been that they keep a register of the names and addresses of those who buy poisons from them. It is quite a common thing nowadays for those who want drugs of all kinds, as well as morphine, to buy from wholesale merchants. In this way they have a triple advantage. 1. They escape the doctors' care and fee. 2. They get the drug cheaper. 3. They get it in large quantities. The retail chemists have become careful not to renew morphine prescriptions too often, and the very fact that they charged a certain sum for such solutions was a check on their being used too much, particu-

larly by such patients as could not afford to pay. But with the new system they get the drug from the wholesale merchant for a low price, and make their own solutions. The following resolutions were passed :

1. That wholesale druggists and manufacturers of pharmaceutical products shall only be allowed to sell morphine and cocaine to regular druggists, and they must deliver it to them by their own men.

2. The retail druggists shall only be permitted to fill a morphine or cocaine prescription once, and they must put the name and address of the person to whom they sell on their own books, and send a copy of the same to the police station of their district, where it must be written on the police report book.

IODIDE OF POTASSIUM.

Dr. Huchard calls attention to the administration of iodide of potassium, and as it is used in large quantities by all physicians, it may be well to give this excellent observer's method. He thinks that the reason why it is not tolerated in some cases, is nearly always because the renal filter does not work well, so that the indications are to add milk and other diuretics to its use. Dr. Huchard gives the following formula :

℞.—Sodium iodide . . . . . 5 grammes
Arseniate of soda . . . . . 0.05 "
Extract of squill . . . . . 0.05 "
Distilled water . . . . . 300 "
Sig. Take two tablespoonfuls per day.

Professor Dieulafoy and Dr. Besnier also give arsenic with iodide of potassium, using as many drops of Fowler's solution as they give grammes of iodide, that is, up to five, six or eight of each. Of course, after that dose, the arsenic is lessened.

EXERCISE.

"*The Pleasure of Movement*," is the title of a late work by a physician who praises exercise in the treatment of diseases. We extract some gems from it: "There is certainly a physical and moral pleasure that accompanies every movement of our bodies. The physical action enables us to get rid of pain, and the moral gives us the satisfaction derived from our fight against the natural forces." "Movements seem to please us the more they are in direct opposition to the laws of gravity. Indeed the dream of humanity seems to be to get rid of gravitation." "Movement, or active exercise, is the best of the anæsthetics ; when ever we accomplish an energetic effort, as long as it lasts, we are almost insensible to pain ; when, for instance, we are immobile, a blow on the shoulder hurts us; but during the excitement of violent exercise (boxing, etc.), some of the hardest blows are not felt at all." "Movements procure a positive physical pleasure, as all the functions are accelerated, the heart beats faster, the respiration increases in frequency and depth, and we feel a sensation of good health ; we live quicker, and are happy to do so; movement will then permit us to flee from pain, and it is also certain that muscular exercise is the best remedy for mental and moral troubles and annoyances."

MEMBRANOUS COLITIS.

The very common affection, spoken of sometimes as *membrano-mucoid colitis*, or, as Dr. Huchard wishes it, "muco-membranous concretions of the intestines," is often seen among women, who are usually constipated, and suffer at the same time from uterine complaints as well, or from neurasthenia. They pass, per rectum, a variable-shaped mass of muco-membranous structure. It would seem that some inflammatory process is the cause, but many think that enteritis is not a necessary element in its etiology. It certainly depends on constipation, bad alimentation, sedentary life, and, perhaps, the arthritic diathesis. Dr. Ringer recommend arsenic for the trouble, but Dr. Brunon lately sums up its modern treatment as follows :

1. Evacuate the fecal matter and eliminate the muco-membranous exudate by the oily purgatives, or with magnesia, podophyllin, or give mercurial purgatives, such as calomel, blue pill, etc., but do not use the alkaline or drastic forms of purgation.

2. Realize, as much as possible, intestinal antisepsis, by rectal injections of solutions of borax. In children this may be done by having powders of bismuth and chalk blown into the rectum.

3. If there is pain, use belladonna, or opium ; the last when no constipation. The nervous element, when present, is best treated with hot baths.

4. The alimentary regimen is one of importance. At first there should be suppression of all solid foods, raw fruit and vegetables. Give raw meat, scraped, and put into a meat soup. All vegetable food must be given mashed into a *puree*, and a little alcohol may be given. The Vichy, Vals and Plombiéres mineral waters are also used to an advantage.

CHLORAL IN OBSTETRICS.

A suggestion in a late paper as to the use of chloral in obstetrics, seems like a good one. It is well known that it is not easy to give this drug when needed in eclamptic fits, as the woman cannot swallow, so that it is mostly used per rectum. But here, again, its effects are often sought for in vain.

The author of the present paper proposes to use an œsophageal sound, putting a wooden wedge between the teeth, and passing the sound with care so that it does not pass into the larynx, which, however, would be quickly noticed, as the respired air would be felt coming from the sound. Having placed it, four to five grammes of chloral in one hundred and twenty grammes of water, is passed per the sound, and a rapid effect is obtained.

TREATMENT OF COLD ABSCESSES AND ADENITIS.

The favorite treatment in Paris in late years has been to inject a solution of iodoformed ether into such abscesses, after drawing more or less of the contents. This, however, causes great pain from the violent distension of the sac that follows the injection ; and the fact is that sometimes the ether causes a profound sleep to follow. It was found also that the iodoform was dangerous, as it might poison a person in cases of large abscesses. This being so, naphthol is now used. It is inoffensive, but it is but little soluble. Prof. Bouchard's formula is used as follows :

℞.—Naphthol beta . . . . . 5 grammes.
Alcohol at 90 per cent . . . . . 33 "
Hot distilled water . . . q. s. ad 100 cubic centimeters.
M.—Filter while hot.

When injecting it, keep the bottle in a hot water bath, and fill the syringe first with a hot antiseptic solution. Evacuate the pus, and inject slowly.

DR. THOMAS LINN.

MEDICO-CHIRURGICAL COLLEGE.

PROF. FRANK WOODBURY, M.D.

GASTRIC CATARRH.

A MIDDLE aged man, who complained of continual pains about the heart. There were no murmurs; appetite was good; was subject to eructations; had slight pain in his head; urine was high colored and acid; there was bad taste in his mouth in the morning; his feet used to smell, but do not at present; there was a feeling of general discomfort and disinclination to work. There was an unpleasant feeling about the epigastrium and back, and a tendency to nausea in the morning. He used alcohol some years ago. The clinician said that drinking cold beer had a great tendency to produce gastric catarrh by its irritation, and increasing the flow of mucus. This patient was hearty and robust in all other respects. His trouble was gastric catarrh. He was recommended to pursue gymnastic exercises, and was allowed no alcoholics. Drinking hot water one-quarter of an hour before meals is an excellent plan. If a teaspoonful of salt be added to a goblet of hot or cold water, and taken before breakfast, it acts as a laxative, and cleanses the stomach. Oxide of silver given on an empty stomach is admirable for this condition of catarrh. As there was fermentation in this case, he was ordered:

℞.—Acidi hydrochlorici diluti, min. xx.

before each meal, to assist the digestion. One-half hour after eating he was to take:

℞.—Acidi carbolici . . . . . ♏ ss.
Tincturæ iodi . . . . . ♏ iij.
M.—Dose.

To regulate his bowels the following pill was to be taken at night:

℞.—Pulv. rhei . . . . . gr. iij.
Podophyllin . . . . . gr. ½.
M.—Dose.

DIABETES INSIPIDUS.

Boy, aged twelve years, was taken with a nervous chill a few months ago, and began to lose appetite and body weight. He was very thirsty all the time, and drank large quantities of water—about six quarts in twenty-four hours. He had no pain or discomfort, but his bowels were constipated. His urine was clear, of low specific gravity—1.001—slightly acid, and showed no signs of albumen or sugar. Patient had good health in every other respect, save that he had an occasional nervous chill. His appetite was poor. He had to pass his water every hour of the day and night. There was no history of injury to the head, or sunstroke, and, in fact, there was no exciting cause that could be absolutely pointed out as the source of the trouble. Being a case of polyuria, he was given codeia, gr. ⅓, four times a day; and in addition, fl. ext. ergot, min. xx, four times a day. This treatment had been followed out, but there was no improvement. The lecturer regarded this as a purely nervous disease of functional character, and so treated the symptoms manifested. He limited the amount of water to be drunk, and urged the use of skimmed milk only, as it contained all the nourishment needed. Three or four quarts daily were allowed, this amount to be gradually reduced in quantity. Patient might use water crackers with the milk. He was now ordered potassium bromidum, gr. xxx, each night, to be increased by 10 grains daily, to control the demand for passing water. Flannel was to be worn next the skin, and the best hygienic habits at all times were to be observed.—W. B. S.

MONTEFIORE HOME, NEW YORK.

SERVICE OF DR. F. S. DENNIS.

OCTOBER 23, 1889.

Leo Ettinger, Resident Physician.

LAPAROTOMY FOR OVARIAN CYST.

THE patient, a young girl, aged seventeen, deaf-mute, had for several years a marked distention of the abdomen. The swelling was painless and gradual in its growth, and occasioned no inconvenience to the girl, and had no effect on her general health, which was good.

The case had been examined by a number of physicians, and considerable difference of opinion existed as to its nature. It was sent to the Home from a metropolitan hospital as a case of tuberculous peritonitis, and was accepted as incurable. Diagnosis before operation lay between peritonitis, encysted peritonitis, ovarian cystoma or papilloma. Dr. S. Baruch made the diagnosis in the case of unilocular papillomata, and the operation sustained his diagnosis. The strong element of doubt in this case arose from the diagnosis of Dr. Walters, who stated that Olshausen, whose clinic she had attended during the year, had three similar cases, which, on operation, proved to be encysted peritonitis.

Operation.

Incision was made through the linea alba to the peritoneum, and cyst exposed; there were no adhesions, cyst tapped, extracted and pedicle tied by the intertwisted suture, and charred by the Paquelin cautery, pedicle dropped, peritoneum, muscles and abdominal walls sutured separately.

The tumor proved to be an unilocular papilloma arising from the hilum of the left ovary. The ovary had degenerated to a hard fibrous ball, the fallopian tube was elongated and adherent over the external surfaces of the cyst.—K. B. P.

DURING six months there were sixty-five deaths at the Norristown Hospital.

SECTARIANISM IN MEDICINE.

WE are hoping to see the day when medicine will be so nearly perfect as a science that sectarianism will be an absolute impossibility. We hope to see all those who practise the medical art universally united upon certain general fundamental principles, and differing only upon matters of minor importance or of doubtful reality. Perhaps the very fact of medicine being an art, as well as a science, precludes every possibility of the realization of such a hope. Hence great liberality must be exercised where the opportunities for differences of opinion are so abundant; neither dogmatism nor sweeping criticism should for one moment be tolerated. As in religion, so in medicine—sectarianism has ever been rife. "Schools" have arisen, and for their dogmatism are as much to be condemned as is the excessive bitterness of those who oppose them in too general a manner, without crediting them with the good they may possess.

In connection with certain endeavors made to secure a State Examining Board, the question of sectarianism in medicine has been recently brought into prominence and made the source of much comment.

At a late meeting of the Philadelphia County Medical Society, two carefully-prepared papers were read, one entitled, Against Sectarianism in Medicine, by Dr. Edward Jackson; the other An Ethical Question, by Dr. S. Solis-Cohen, both of which elicited a considerable amount of earnest discussion. Dr. Jackson took the ground that all intelligent men should be respected for their convictions, and that differences of opinion so common in the profession generally should not be made the means of preventing that fellowship and union necessary to the furtherance of scientific knowledge. Referring then more particularly to the homœopathic school of medicine, he declared that its professors should not be criticized by the doctrines of homœopathy as taught in the *Organon*, since few of them at the present day practise these old teachings. Hahnemann was a reformer who did much to correct old abuses; but, like all reformers, was led too far by his enthusiasm. The practical homœopathists of the present time admit the good work of Hahnemann; but they recognize his errors and so exercise a more liberal profession, consistent with the broader idea of a physician. To substantiate his position, the author of the paper quoted from the Announcement of the Hahnemann College, of Philadelphia, showing that there they use the same text-books, teach the same subjects, and require the same amount of practical work as most of the so-called regular colleges. We have no reason, he said, to think that these subjects are less thoroughly taught, or that they are more ignorantly practised by the homœopathists than by the regulars.

Dr. Solis-Cohen's paper was a much longer and stronger argument, based upon the general assumption that a man must be credited for practising what he professes to. A large part of the paper was occupied with quotations from the *Organon*, and comments upon the same to demonstrate the absurd, unscientific, and mystical teaching of Hahnemann. The writer then clearly asserted that men who bear the name and practise under the colors of homœopathy must be considered as believing and practising those teachings if they are honest men. If they do not believe and practise homœopathy, as Dr. Jackson seemed to insinuate of most of them nowadays, and they still continue to avail themselves of all the advantages which the term *homœopathy* has with the laity, they are then not honest, and are simply practising deceit. In either case, a regular physician—who is honest to himself and to the laity—cannot consult with gentlemen of the homœopathic school, for in the first instance the consultation would be simply null and void, the homœopath holding to his tenets, and the regular regarding those tenets as absurd; and in the second instance he would be the abettor of fraud and dishonesty, the homœopath failing to practice what he publicly professes. Such, in brief, is the outline of the arguments of these two papers.

Unity in the profession is undoubtedly most desirable; but unnecessary and harsh criticism is not the best means of attaining that end.

It is true that we must respect men for the honesty of their convictions; but that is something quite different from respecting the convictions themselves. We confess our admiration for a homœopath, or any other "path," who honestly practises what he believes, and has the boldness to stand out publicly for his beliefs. But if it be true, as Dr. Jackson insinuated, and as Dr. Wirgman declared had been told to him by a prominent homœopathist, that in this city alone, out of two hundred and fifty pro-

fessors of the doctrines of Hahnemann, only seven were true homœopathists, no severer criticism need be offered against the school, for they are then nothing more, nothing less, than medical men making use of a trade-name to further their own private interests. Again, to assert that these gentlemen are *non compos mentis* because they are honest enough to stand by the doctrines of their great teacher, is both untrue and entirely gratuitous. Granting that they are honest in their convictions and practices, their peculiar experience or modes of reasoning may be such as to lead them into the homœopathic way of thinking, and no other. If they are true to their profession, we repeat that we admire them, though we cannot sympathize with them in their beliefs.

It seems, after all, that the great bugbear in regard to consultations between the regular physicians and the homœopathists is the name *homœopathy* itself. If a name is to be no indication of a man's views, then consultations with and the endorsement of eclectics, metallotherapists, mesmerists and Christian scientists would be quite proper, if we could only be assured that they practised upon a rational, scientific basis, regardless of what they professed or what absurdities might be involved in the terms of their profession. But this statement of the case is a *reductio ad absurdum*, and amounts simply to an impossibility.

We have occasionally met men of high intelligence among homœopathists, and we would like to have the honor of ranking them on the roll of general physicians, free from all dogma, and striving only to cure the ills of humanity in whatever way a broad and liberal science dictates. We would like to see them drop the term homœopathy with all the narrowness and dogmatism attached to it by Hahnemann, who first employed it and gave it its meaning. If they are really practising medicine upon general principles, let them decline boldly and honestly to bear any sectarian name, and so aid in promoting the union of the profession. If, however, they are homœopaths and Hahnemannians still, let them stand honestly by the doctrines attached to the name they bear, and we will be glad to grasp their hands out of the respect we bear them for the honesty of their convictions, though we may differ from them as to the value of those convictions.

MERCURY IN CONSUMPTION.

INCREASED knowledge often displays in a more glaring manner one's own weakness and inability. It is so in all departments of science, medicine included. Before the invention of the telescope and discovery of the celestial systems, man imagined that he and his little earth were the centers of all things created; he foolishly thought that in himself was the only expression of force and intelligence. In the light of these latter day revelations he now beholds his own ittleness and physical weakness. Since the discovery of the bacillus of Koch, our knowledge of phthisis pulmonalis has become so accurate that scarcely any disease is capable of being diagnosed with greater certainty; yet in regard to its treatment we have not advanced one iota beyond the older methods, but instead have become more hopeless of being able to attack the origin of the trouble itself. After having studied the vital history of the bacillus and experimented in every possible way to destroy it when it has once entered the tissues, we are compelled to think that such a very desirable result is well nigh impossible. Hence we must still rely upon the earlier plans of treatment, empirically wrought out long ago, namely those of prophylaxis and hygiene.

There are some who are beginning to believe that after all tuberculosis is to be classed in the same category with scrofulosis, syphilis and similar constitutional affections, and that the bacillus is but a secondary product, finding in the first named disease its most favorable conditions for development. In accordance with these views hygiene is the only proper basis for the prevention and rational cure of tuberculosis.

The surest prophylaxis is to keep the constitution at the high-water mark of health; when the disease has once effected its invasion, the only proper treatment is to restore and keep the organism in a vigorous state. Tonics of all sorts have been tried for this purpose, among them the preparations of mercury.

Notwithstanding the experience of a thousand years' summed up by Collin in the remark that "mercury is pernicious in consumption," the treatment has been revived and extensively studied during the past year. Martell, of Breslau, concluded after a three years' investigation (*Wiener Med. Wochenschrift*, July 1, 1889) that *calomel* is the best adapted specific antiseptic in the treatment of tuberculous conditions. Dochmann declares (*Therapeut. Monatshefte*, September) that the same remedy exercises a favorable action in the ordinary forms of anæmia, even where iron has been ineffectual; it stimulates the appetite, removes habitual constipation and regulates menstruation.

Mercury, in small doses, is undoubtedly a tonic; in large doses it is debilitating and fatal. Prof. Edward L. Keyes, of New York, published an article in the January number of the *American Journal of Medical Sciences*, 1876, giving the results of his experiments with mercury in modifying the number of red blood corpuscles in syphilis. He asserts that mercury decreases the number of the red blood corpuscles when given in excess; when given in smaller doses, continued for a short or long period in syphilis, alone or with the iodide of potassium, it increases the number of red corpuscles, and maintains a high standard of the same; given in the same way to individuals in fair health, not syphilitic, it is a tonic for a time at least, here likewise increasing the number of the corpuscles.

Dr. John R. Hall, of Marshall, Mo., has published

a paper in the present number of the same journal, reporting his experience along with a number of cases in which the iodine and mercurial treatment was tried in incipient phthisis. He says: "About eight years after reading Prof. Keyes' article, I first administered small doses of bichloride of mercury with potassium iodide to patients suffering from phthisis, with a result which, compared with former experience in such cases, was no less surprising than gratifying."

The common symptoms exhibited more or less by all his patients were a frequent pulse, elevated temperature, wasted or wasting body, loss of appetite, cough, often accompanied by bloody expectoration, pulmonary dulness on percussion, increased vocal resonance, prolonged expiratory murmur, moist râles, etc. The mercury was given in doses of one-thirty-second to the sixteenth of a grain, and the potassium iodide from two to five grains, three times a day. A marked improvement was the result in most of the cases, and in a small percentage a cure seems so far to have been obtained. The only allusion to the use of mercury in this way found by the author, was a paper read May 22, 1888, by Dr. L. N. North, of Brooklyn, who says that "the chlorides of mercury, especially the bichloride, have, I believe, been the means of doing much good," and are therefore to be placed among the number of remedies beneficial in consumption. There is nothing specific in the action of mercury employed in this manner; its beneficial action is undoubtedly due to its effects upon the processes of nutrition. Syphilitic phthisis does not differ in its anatomical aspect from the non-specific or ordinary sort, hence the action of the mercurial is not dependent upon its antagonism to the syphilitic poison entirely.

The iodide treatment we have had some slight experience with, but the results were not sufficiently favorable to induce us to continue it long enough for the purpose of comparison. The theoretical considerations for the employment of iodine and its compounds, have not been supported by the clinical results. The use of the mercurials in combination with the iodides, however, may prove more beneficial, not from any theory of their specific action, but from the simple observations of their effects upon nutrition. This treatment is therefore applicable to all diseases characterized by emaciation, diminution or destruction of the red corpuscles, and fibrous infiltrations. If these symptoms are characteristic of consumption, and usually they are when it is in its incipiency, the use of the mercurials combined with the iodides, is both rational and deserving of more extensive trial.—L. H. M.

A MEDICAL UTOPIA.

IN the great socialist novel, "Looking Backward," the author thus describes the status of the physician under the new dispensation: "The good a physician can do a patient depends largely on his acquaintance with his constitutional tendencies and condition. The patient must be able, therefore, to call in a particular doctor, and he does so, just as patients did in your day. The only difference is that, instead of collecting the fee for himself, the doctor collects it for the nation by pricking off the amount, according to a regular scale for medical attendance, from the patient's credit card. We have no poor doctors. Anybody who pleases to get a little smattering of medical terms is not now at liberty to practise on the bodies of citizens, as in your day. None but students who have passed the severe tests of the schools and clearly proved their vocation are permitted to practise. Then, too, you will observe that there is nowadays no attempt of doctors to build up their practice at the expense of other doctors. There would be no motive for that. For the rest, the doctor has to render regular reports of his work to the medical bureau, and if he is not reasonably well employed, work is found for him."

It is questionable if there are many physicians who would not welcome a rearrangement of society which would relieve them of all necessity of "taking thought for their future," or providing for the rainy day, which would remove all fear for the future of their families, enable them to devote themselves heart and soul to the work of their profession, and retire from active participation in it at the age of forty-five, to spend the remainder of their lives in recreation, travel, study, and the working out of theories suggested by their previous experience. Such a system is in strict harmony with the ideal of a profession as distinguished from a trade; and it is somewhat remarkable for a layman to take the same stand in regard to the limitation of the right to practise to those who first approve their fitness, and also to place the profession upon the highest ethical plane. And if the standard so long upheld by the profession be the one right and proper for the physician, it would seem not unnatural to infer that it might be as well suited to the rest of mankind. Mr. Bellamy should, therefore, find numerous supporters in our ranks for a scheme of a new Utopia—or a new Christendom.

Annotations.

THE FALLIBILLITY OF EXPERTS.

HOW much longer will common sense be overruled by what is called "expert evidence?" Nellie Bly, the New York correspondent, was adjudged "hopelessly insane," committed to an asylum and kept for ten days under a close guard by one of these experts, and when he was confronted with the published account of his atrocious ignorance he justified it by saying the woman "lied;" that she had merely pretended to be insane. Presently a man will justly be regarded with suspicion and dread who calls himself an expert.—Washington *Post*.

This is worse than the usual ignorance of the newspaper writer who meddles with such matters. Any

one of ordinary intelligence can study up the symptoms of insanity, and simulate them in a way calculated to deceive an expert, *whose attention has not been attracted to the question of malingering*. For instance, a man who is said to be insane, in his conversation with us imparts the information that he is the Grand Mogul, and has a mission on earth to raise a pyramid of human heads equal to Tamerlane's. We are informed by his friends that he has made attempts to begin this structure by cutting off his mother's head; furthermore, he is a person whose condition does not suggest the question of malingering. If the man admits his attempt at murder and attempts to justify it by an insane delusion, there would not only be sufficient grounds for certifying to his insanity, but the physician would be culpable in not using his influence to have the man confined as a dangerous lunatic. And if it subsequently turns out that the whole story is untrue, the delusions simulated, and the alleged lunatic is a reporter in search of a sensation, we do not see how the expert is to be blamed, or by what process he is supposed to detect the imposture.

THE HAMMOCK CURE.

THE author of the suspension treatment for ataxy now states that he obtains equally valuable results by swinging his patients in a hammock. The distinguished specialists who have been causing new nervous tissue to grow where the original is destroyed, by means of the suspension method, will doubtless exploit the hammock cure; especially as they have been suspiciously silent of late concerning the suspension method. It is about time for a new sensation (especially since that eminent worshipper of gig-respectability, the *Ledger*, has informed the medical profession that it mustn't investigate the Brown-Séquard theory) and the hammock cure has some very attractive features to recommend it. It will be popular with the fair sex; the hammock being susceptible of varied and effective ornamentation by ribbons, etc., and requiring the strength of a masculine arm to keep it in motion. Very charming costumes can be designed for it, and the daintily slippered foot cannot possibly be hidden entirely. A page in buttons is requisite to drive away errant insects, and see that no wandering caterpillars molest. As the picture develops it really looks as if fame and fortune await the man who popularizes this new method.

Letters to the Editor.

THE TEETH IN NEURALGIA.

A CERTAIN amount of attention is often necessary in order to avoid mistaking true neuralgia for other analogous affections. It is most frequently mistaken for the pain arising from decayed or newly erupting teeth; but a careful examination of the mouth will soon disclose the trouble, if from the teeth, and the proper treatment of the same will eradicate supposed neuralgia. But no amount of dental treatment will remove the pain of true neuralgia; in fact, such treatment has a general tendency to aggravate the pain. The following case is given as an illustration, and is one of many wherein the aforesaid mistake in diagnosis caused unnecessary suffering to the patient.

Miss J., age twenty-two, had been under treatment for what her medical adviser told her was true neuralgia of the inferior dental nerve. For the last six months experiencing no relief under the treatment, she put herself under my care. The location of the pain suggested to my mind an abscess or exostosis of the left inferior bicuspid tooth. I made a thorough examination of all the teeth, and, except for a deciduous left inferior molar, I found the mouth and teeth in a normal condition. The molar I removed, and afterward, in probing into the cavity, I struck the unerupted second bicuspid tooth. In a few days this had completely erupted, and the patient has been free from pain since. The pain naturally arose from an irritation of the nerve of the bicuspid, caused by pressure of the molar on it during mastication, as the patient experienced the most pain during that act.

In conclusion, I would say that in all cases of true or supposed neuralgia of the trigeminus, the first course to pursue is to give the mouth and teeth a thorough examination, for it will be found that, in a vast number of such cases, here lies the seat of the trouble.

DR. WILLIAM M. ROSENTHAL.
CHICAGO, ILL.

Society Notes.

AMERICAN RHINOLOGICAL ASSOCIATION.

Seventh Annual Meeting, held at the Palmer House, Chicago, Ill., October 9, 10, and 11, 1889.

OCTOBER 9. FIRST DAY—MORNING SESSION.

THE Association was called to order at 10 A. M. by the President, DR. JOHN NORTH, of Toledo, Ohio.

The following were elected Fellows of the Association: Dr. E. L. Siver, Fort Wayne, Ind.; Dr. C. L. Dreese, Goshen, Ind.; Dr. C. F. McGahan, Chattanooga, Tenn.; Dr. Ely McClellan, Chicago, Ill., and Dr. L. B. Gillette, Omaha, Neb.

The next thing in order was the President's address, which dwelt (1) with the relations that the physician bears to the public; (2) the relations of the specialist to the general practitioner and other specialists, and (3) what the American Rhinological Association has done for the public and for the profession.

A paper by Dr. L. B. Gillette, entitled

REPORT OF A CASE OF BRAIN ABSCESS, EMPTYING INTO THE NASO-PHARYNX,

was read by title.

The patient, aged twenty years, farmer by occupation, strong and healthy, while working on an embankment in September last with a wheel scraper, in driving along with it loaded, it in some way became unlatched and the handle in flying up struck him forcibly under the chin, knocking him down a sixteen-foot embankment, where he lay unconscious for thirty minutes. A week afterward he noticed

that something was wrong with his eyes. About the 15th of October he went to work in a brick-yard; worked three days, and then complained of being nervous and of having a slight headache. On the evening of the third day he got soaking wet in a rain, went home cold, had a chill, followed by fever. A physician was called, and pronounced it malarial fever. Dr. Gillette being subsequently called to see the case, found the patient suffering with intense headache, the pain extending down between the shoulder blades, and particularly into the right arm. Both pupils were widely dilated. Temperature was 101°; pulse, 105. He knew he had an inflammatory condition to deal with. A day or two after his advent into the case there developed marked compression of the brain. Temperature went down to 96°; pulse as low as 42; respirations to 9 or 10. Complete paralysis of right side, and partially of left; complete loss of sensibility as well as of consciousness. He also lost the sense of sight, and remained in this condition four days, without any perceptible changes whatever. The patient took his food and medicine regularly. He was surprised one morning on finding that the patient had much improved. The mother told him that during the night the patient had a violent attack of coughing, and showed him the character of the sputum. It was about an ounce of green, stinking pus, mixed with mucus. From this time the patient began to improve. There was an immediate return of consciousness, a quickening of the heart's action and respirations. Examination of the throat showed that the pus came from above. No pus came out of the Eustachian orifices, and when the patient leaned forward it would come out of the anterior nares. The discharge lasted two weeks. Where it came from, or how it got through, he could not tell. His opinion favored the ethmoidal and sphenoidal sinuses. As a result of this terrible ordeal the patient, when seen three months since, was totally blind, sense of hearing lost in right ear, has not got the use of his right arm, and his mind is not what it was. Could such results take place without some destruction of the brain tissue proper? Could the patient have the same results from an *intra-meningeal accumulation?*

In the treatment Dr. Gillette used opium, quinine, mercury, cold applications to the head, and cupping at the back of the neck, and the triple bromides as they were indicated. As soon as marked compression of the brain had developed, he began to use eighty grains of iodide of potash each day, and kept it up for thirty days. Did this treatment have anything to do with the results?

Dr. Thomas F. Rumbold, of St. Louis, read a paper entitled

REASONS WHY SO MANY PHYSICIANS FAIL IN TREATING CHRONIC RHINITIS.

The (1) is *defective instrumentation.* Not one of the physicians whose offices he had visited had a tongue depressor that would not cause the patient to retch as soon as it was introduced into the mouth. The blades of all the instruments he saw were too wide to go between the the teeth, and too long—being about six inches in length. These instruments were seldom used in examinations, the exceedingly defective method of drawing the tongue out with a napkin being employed instead.

2. The *spray-producers* used were made for watery solutions only. These physicians did not possess an instrument that could throw warm vaseline. Liquid cosmoline was found in every office. While this remedy is far superior to tannin, iodine, nitrate of silver, or any of a dozen other agents commonly found in offices, yet it is much inferior to warm vaseline.

3. The *compressed air* used was taken from a container of a capacity of from three to four or five gallons. Air enough was forced into this reservoir to show a pressure of from thirty to seventy pounds. The reservoir was filled by an air pump whose barrel was made of brass; the piston was packed with leather—which is partially-decomposed animal tissue—and it was lubricated with rancid oil of some kind. Ten pounds is the greatest pressure that the mucous membrane can stand without producing irritation, while by far the greater majority of patients require from only six to eight pounds pressure.

4. Reason for failure is an *anatomical* one. He meant by this an error in locating the disease. Innumerable clinical observations and post-mortem examinations prove conclusively that rhinal inflammation invariably commences on the superior and middle turbinated processes, and extends in all directions in the nasal passages, and into the passages connected with them, except on the floor of the nasal passages or so-called inferior meatuses. These two portions are seldom affected with inflammation.

5. The *physiological* reason.

Other reasons were *pathological* and *etiological.*

Keeping in mind that every irritation produces inflammation, what are the indications for treatment of chronic rhinitis?

(*a*) The diseased secretion, which is always acrid, therefore irritating, should be removed. If morbid growths are present, as these also are irritating, they should be removed, thus removing the local sources of inflammation.

(*b*) The new secretion, that is, that which is to be formed upon the surfaces that have been cleansed, should be prevented from becoming acrid, thus preventing another cause of inflammation.

(*c*) Hygienic and sanative measures should be insisted upon. This is to prevent a continuance of the irritation to the sensory nerves that are located upon the surface of the body and mucous membrane, by colds and other irritating agents, thus removing the originating causes of the inflammation.

Dr. A. de Vilbiss, of Toledo, in opening the discussion, differed from Dr. Rumbold in that he did not believe properly tanned leather readily decomposes. Rancid oil for lubricating the air pump is hardly ever used. Personally, he used vaseline and naphthol. With regard to vaseline, it was used as a protector to the mucous membrane on account of its density.

Dr. C. F. McGahan, of Chattanooga, heartily concurred in what Dr. Rumbold had said regarding vaseline. Where we want the surface protected

nothing will better take the place of vaseline. He sometimes uses iodine in weak solutions, and has not as yet had any bad effects from it.

Dr. A. G. Hobbs, of Atlanta, uses the oil of vaseline. *First*, for cleansing purposes, and *second*, for its celerity. He can warm it much quicker than the solid vaseline. The danger and greatest objection to the douche, in cleansing the nasal passages, is its liability to set up middle ear catarrh, which is sometimes produced by the post-nasal and anterior nasal douche.

Dr. John North, of Toledo, did not favor the use of tongue depressors. Patients should be trained to manage their tongues without them. When he did use one, it was a small, wire tongue depressor. He uses the oil of vaseline for cleansing the nasal passages with a little alkaline spray, or even with eucalyptus, or some other antiseptic dissolved in it. High pressure the rhinologist did not want.

Dr. C. L. Dreese, of Goshen, Ind., read a paper on

REFLEX SYMPTOMS OF RHINAL DISEASES, WITH REPORTS OF CASES.

The *first* case was one of heart, stomach, and lung troubles, caused by sympathy from rhinal disease. The removal of the latter affection was followed by recovery of the former. The *second* case was one where incontinence was a reflex symptom of chronic nasal catarrh, and was cured by treating the catarrhal trouble alone. The *third*, in which epilepsy was a complication of rhinal disease.

Afternoon Session.

Dr. C. H. Moore, of Indianapolis, contributed a paper on

OCULAR REFLEX SYMPTOMS IN NASAL DISEASES.

He had relieved a case of neurotic affection of the Eustachian tube of the left ear by spraying the nasal passages with vaseline. Hack mentions a number of cases of hemicrania and asthma cured by the galvano-caustic destruction of the hyperplasia of corpora cavernosa of the nasal cavity. Voltolini demonstrated that asthma may be relieved by the removal of nasal polypi. A certain group of eye symptoms, such as lachrymation, photophobia, conjunctival hyperæmia, are observed in a number of patients that come to the rhinologist, and yet the examination of their eyes reveals no anomaly, the vision normal, no eye strain, conjunctivæ healthy, the puncta lachrymalia favorably placed, and the tear ducts open. For such cases a simple eye wash has been ordered, cold or warm applications recommended and general hygienic treatment advised without any relief to patients. Relief of the rhinal affection in these patients was generally followed by a cure.

The cases he reported had the following symptoms in common:

1. Burning and smarting sensation of the eyelids, especially in the morning.
2. Difficulty to distinguish an object in an ordinary daylight.
3. Increased vascularity of the conjunctivæ and lachrymation on exposure to the air.
4. The sound condition of the eyes and their appendages.
5. Failure of ocular and general treatment.
6. The efficiency of nasal treatment.

Dr. N. R. Gordon, of Springfield, Illinois, said his rule of proceeding with such cases is to examine the eyes for irritation or the condition of refraction, and if the latter is normal and no other source of irritation can be found in the eye, he examines the mucous membrane of the nasal passages, and very often the cause is to be found there.

Dr. R. E. Lewis, of Indianapolis, said there was no doubt but that a number of such cases are being constantly referred to the rhinologist. It should be determined that there is no error of refraction requiring treatment before the rhinologist accepts the case. About one-third of his cases were sent to him by Drs. Thompson and Stillson (oculists), but not until the eye trouble has been corrected, after which he commenced to treat them for rhinal troubles. This he believed to be the logical course to pursue in such cases.

Dr. E. Fletcher Ingals, of Chicago, related the case of a lady which illustrates the possibilities of eye trouble being caused by nasal disease. She came to him with hypertrophic rhinitis. He proceeded to cauterize the turbinated bodies, and before she left the office she asked him if he could not do something for her eyes, that she was unable to use them more than five minutes at a time for the last three years. He referred her to an oculist that she might get relief. She did not return to his office for two weeks; on her return, she said she had not been to an oculist, but that the next day after the nose had been cauterized she was able to read at night, and it did not affect her eyes.

Dr. N. R. Gordon read a paper on

THERAPEUTIC MEASURES IN RHINOLOGY.

He said that after the surgical removal of hypertrophoid tissue, a curative local treatment, continued at short intervals for one or two years, or even longer, is necessary. This should consist of the oil of vaseline, with a small amount of eucalyptol, or something of that character. Astringents do but little, if any, good. Where the oil of vaseline fails salt and water in proper proportions with a small amount of listerine, or Dobell's solution, are suitable remedies. To prevent mouth breathing during sleep, he recommends his patients to wear a little instrument made of celluloid that fits neatly between the teeth and lips.

In atrophic catarrh, after the removal of all secretion on the surfaces, where the mucous membrane is very thin, or even ulcerated, he finds the application of a solution of *resorcin*, one drachm to the ounce, to be exceedingly beneficial. In the most unyielding and obstinate form of nasal catarrh he uses a glycerine suppository, composed of 95 per cent. *glycerine* and 5 per cent. *stearin*. The solidified glycerine is placed so as to come in contact with the atrophoid, or ulcerated portion of membrane. The glycerine soon asserts its well-known affinity for water, and the result is an abundant flow of thin mucus.

OCTOBER 10—SECOND DAY—MORNING SESSION.

DR. C. H. VON KLEIN, of Dayton, Ohio, read a paper entitled

ATROPHY, HYPERTROPHY AND DEVIATIONS OF THE SEPTUM,

in which he said he had examined the nasal cavities in over 600 patients, and found not exceeding two per cent. to have an absolutely straight division of the nares. In almost every case he observed deformities of some sort, either atrophy, hypertrophy or deviation of the septum.

The causes which are most common to deviation of the septum, occur to people when they are in their babyhood. When children commence to creep and walk around, passing from chair to chair, they fall, and nine times out of ten it is on their nose. Personal observation leads him to believe that *atrophy* of the septum is confined to the cartilaginous portion. *Hypertrophy*, on the other hand, is confined to the osseous portion of the septum, and these conditions are generally caused by such injuries as may occur to any other part of the bony system. A stroke or fall on the osseous portion of the septum may produce hypertrophy.

The paper was followed by one on

THE TREATMENT OF CHRONIC NASAL CATARRH,

by DR. C. F. MCGAHAN, of Chattanooga. (See page 649.)

AFTERNOON SESSION.

DR. A. DE VILBISS, of Toledo, contributed an interesting paper entitled

SURGICAL TREATMENT IN DISEASES OF THE NOSE.

in which he said, until recently few diseases have caused more dissatisfaction in their treatment than chronic nasal catarrh. He did not wish to be understood that in every case of nasal catarrh there is a demand for surgical interference, but in every case that demands operation, a catarrhal condition of the nasal passages was usually found to exist. He had given relief from frontal headaches, mental depression, etc., by the removal of the hypertrophic tissue from the middle turbinate. He believed the time was not far distant when the sphenoidal sinus, frontal sinus, post and anterior ethmoidal cells (after death), would be looked into and examined, to find a special cause for certain symptoms that existed during life, and the answer found. Schwable, Axel Key and Retzius have demonstrated the fact that not only can the lymphatics of the nasal mucous membrane be injected from the sub-dural and sub-arachnoidal spaces, but if force be used the fluid will pass through the lymphatic canals to the surface of the nasal mucous membrane. Permanent nasal stenosis should be relieved by an operation, as it is due to either traumatism, hypertrophic tissue over turbinate bones, thickening of tissue or deflections of nasal septum, gelatinous polypi, adenoma of vault of pharynx, fibromata or sarcomatous tumors, and the only source of relief is their removal or correction of misplaced parts. Preparatory to operating he always cleanses the naval cavities of acrid matter, and protects the cut surfaces, after operation, by keeping them covered with iodized or carbolized albolene or vaseline. Hemorrhage, if necessity demands it, he controls by cotton plugs. If the source of hemorrhage is well back in the nasal cavities, he uses small cotton plugs tied with a string in the form of a kite-tail, which are easy to introduce, and easy to remove.

A paper by DR. E. L. SESSIONS, of Hillsboro, Texas, entitled

THE ADMINISTRATION OF QUININE WHERE THERE IS DEFECTIVE HEARING,

was read by title in the absence of the author.

OCTOBER 11—THIRD DAY—MORNING SESSION.

At the solicitation of Dr. Seth S. Bishop, of Chicago, a committee was appointed by the President to co-operate with the United States Hay Fever Association with reference to the investigation and treatment of hay fever,—to report annually.

DR. R. S. KNODE, of Omaha, contributed a paper on the

IMPORTANCE OF CONSTITUTIONAL TREATMENT IN RHINO-PHARYNGEAL INFLAMMATIONS,

in which he said the rhinologist ofttimes becomes discouraged with all the means at his command, when he finds that patients do not improve as he would like them to do; but if the history is carefully looked into there would be found some diathetical condition at the bottom of the nasal trouble, which, if the rhinologist could relieve, would cause a subsidence of the local inflammation. This catarrhal condition frequently extends into the stomach and intestines, and from the duodenum to the ductus choledochus, in which we have the combined symptoms of gastro-intestinal catarrh associated with jaundice, and when the nutritive system becomes implicated, there is a wide range of sympathetic disturbances which invariably follow.

The principal sympathetic phenomena transmitted from this condition are sick headache, depression, melancholy, sleeplessness, hypochondria; the heart's action is often disturbed; there is sympathizing dyspnœa, and to these may be added languor, lassitude and irritable temper.

The general principles in the treatment of such cases would be a properly restricted diet, consisting of milk, stale bread, soft boiled eggs and well-cooked rice. If milk is not well tolerated, it should be peptonized; foods containing little starch and largely diluted with water are the best tolerated. Among the internal agents may be mentioned the alkaline carbonates, combined with purgative salines, especially where the nasal trouble is associated with disease of the stomach, which is a frequent complication in malarial districts. And in these regions no treatment is effective until we diminish the engorgements of the liver and spleen, and nothing accomplishes this so well as the use of alkalines and saline laxatives, and these may be assisted by small doses of mercurials. Carlsbad and other mineral waters have been extolled; but phosphate of soda and Rochelle salts, if perseveringly used, may take their place. General hygienic treatment in all cases must be insisted on.

REFLEX INFLAMMATION OF THE NOSE AND THROAT was the title of a paper by Dr. E. L. Siver, of Fort Wayne, Indiana.

The author reported a case of laryngitis with aphonia which lasted two weeks, and which he thinks arose from a deflected septum and posterior hypertrophy of the inferior turbinated bone.

Dr. A. G. Hobbs, of Atlanta, read a paper on

CATARRHAL NEURALGIA,

by which he meant to include not only the headaches and brow-aches which are caused by the pressure from nasal hypertrophies or foreign bodies, but all reflex pains that have for their origin pressure in the nasal cavities, whether they be located in the forehead, the temples, across the bridge of the nose, or over the cheek bones. That such reflex pains do occur, and have for their cause pressure in the nasal cavities, was known long ago. If they were only occasional or of short duration, they might not demand so much attention; but in many cases the pains are more persistent than the neuralgias from any other cause, and they many times produce a more profound impression upon the general system, indicated by a sense of lassitude, a haggard expression, a malassimilation, and a decided loss of weight. He had no statistics bearing upon the comparative frequency of catarrhal and ocular neuralgias other than his own note-book of the last three years. In it he found fifty-four cases under the combined headings: *Catarrhal neuralgia, ocular headache, and catarrhal and ocular neuralgia* combined; 36 cases occur under the first caption; 14 cases under the second, and 4 cases under the third.

After recognizing the ætiology of a case exhibiting these reflex pains, on account of the severity of the pain, temporary relief should be given the patient by the application of cocaine sprays, or in the case of complete stenosis, the cotton probe saturated with cocaine first; then the sprays. The effort should then be made to reduce the pressure permanently by the means that is most rapid.

If the pressure be due to a polypus, extract it; if to a deflected septum, remove the deflection; and if it be (as is most likely the case) due to an hypertrophy, reduce it with the galvano-cautery, the snare, glacial acetic acid or chromic acid. He most frequently resorts to the latter. After the removal of the pressure, pain ceases to a great extent, if not entirely; then the more soothing treatment of vaseline sprays in combination with cocaine, pinus canadensis, oil of terebene or oil of eucalyptus, daily or tri-weekly, will complete the resolution.

He knew of no class of cases that applied to the rhinologist for relief in which treatment gives more prompt and satisfactory results. Indeed, when there is no mistake made in the ætiology, the result is absolutely sure, if means are resorted to that are effectual in removing the pressure upon the terminal sensitive nerves that are distributed to the nasal mucous membrane.

Dr. Ely McClellan, of Chicago, read a paper on the

PHYSIOLOGICAL AND THERAPEUTIC ACTION OF CERTAIN DRUGS IN THE TREATMENT OF AFFECTIONS OF THE UPPER AIR-PASSAGES.

Officers for 1890.—President, Dr. A. G. Hobbs, Atlanta, Ga.; First Vice-President, Dr. A. B. Thrasher, Cincinnati, O.; Second Vice-President, Dr. E. R. Lewis, Indianapolis, Ind.; Secretary and Treasurer, Dr. R. S. Knode, Omaha, Neb.; Librarian, Dr. John North, Toledo, O., Member of Council, Dr. C. H. Von Klein, Dayton, O.

Next place of meeting, Louisville, Kentucky, 1890, in conjunction with the Mississippi Valley Medical Association.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated meeting, October 21, 1889.

C. S. Wood, President, in the Chair.

RESOLUTIONS on the death of Dr. A. B. Mott were read by the Secretary and adopted.

Dr. John Shrady read the biography of Dr. Mott, mentioning his distinguished services as Medical Inspector in New York during the late war, his efforts in founding St. Vincent's Hospital and Bellevue Medical College. Dr. Mott was a member of many medical societies, and a 33d ° A. A. S. R. Mason. The paper of the evening was read by Dr. Geo. T. Harrison.

PODALIC VERSION IN CASES OF CONTRACTED PELVIS.

Dr. Harrison gave as his opinion that version was safer than forceps, in cases of gesto-minor or flat pelvis.

In the discussion which followed, the method of Braxton Hicks was warmly recommended, the external method of Pinard not coming under consideration.

A second paper was read by Dr. A. M. Fernandez, on

DOUBLE MONSTERS,

with exhibition of a specimen.

September 13, 1889, Dr. Fernandez was called to a young woman aged twenty-three, native of Nicaragua, married one year, who was on a visit to this city. She was in her sixth month of utero-gestation, and during the evening felt a dribbling of water down her legs, accompanied by slight pains in the abdomen. Ordered strict maintenance of recumbent posture and gave morphine. At 10 P. M., true labor-pains came on. Woman refused examination; so waited with patience until 12.30 A. M., when she begged relief. At 1 A. M. consented to an examination, and to my great surprise found three feet protruding through the vulva; thought it was twins; tried to push up third leg, but did not succeed; then sent to New York Hospital for a physician to consult with. Dr. Frank Wilson, the ambulance surgeon, responded to my call. We both examined the case carefully. I decided to do nothing, but let "Dame Nature" have her way. We succeeded perfectly, for while Dr. Wilson was holding the legs and I was rubbing the perineum with oil, the fourth leg

came down, and soon the hips were born; a spiral motion of the body (internal rotation) then took place, and the heads were soon delivered.

Description of the monsters (Thorapages): This specimen belongs to Class A of Playfair's scheme.[1] "Two nearly separate bodies, united in front to a varying extent by the thorax or abdomen." In my case the children are united along the sternum, both male; one measuring 14 inches in length, the other 13; circumference of heads, 10¼ and 11½ inches; circumference at pelvis, 13 inches. By this description, you will see there is a similarity between my case and the bond of union in the celebrated Siamese twins. The doctor then read a series of extracts carefully culled from the Index Medicus and Surgeon's General Catalogue.

There was no discussion, as no other member has had the fortune to meet such a case. —K. B. P.

HARLEM MEDICAL ASSOCIATION.

Stated Meeting, October 2.

Dr. M. C. O'Brien, Vice-president, in the Chair.

Dr. Swineburne presented a case of an electrician, aged thirty-four, no specific disease, who consulted him for defective vision of left eye. Examination revealed a slight paralysis of the external rectus of that eye. Next day, while reclining in a horse car, he suddenly became unconscious, and remained so for forty-eight hours, and was confined to bed for one week. To-night, as you can see, the external rectus is somewhat paralyzed, which, combined with shortening of the internal rectus, produces an internal strabismus. Ophthalmoscope discovered fundus normal.

Dr. Mallesons, who had attended patient during his illness, stated temperature was subnormal, pulse low (50), he never had rheumatism, complained of pain over apex of heart, and had double mitral murmur, albumen in urine.

Dr. D. C. Cocks thought absence of fever, with rapid recovery, tended to exclude cerebral hæmorrhage, and thought coma was due to the systemic effects of albuminuria, and not due to nuclear trouble. These peculiar eye troubles have been known to antedate posterior spinal sclerosis.

Dr. H. J. Wolf examined patient, found reflexes normal. He had seen a case which verified Dr. Cocks' statement, where paralysis of the rectus muscle preceded locomotor ataxia.

Dr. Swineburne presented a young girl suffering

FROM DIPHTHERITIC PARALYSIS OF THE PALATE, AND PARALYSIS OF THE CILIARY MUSCLE OF THE RIGHT EYE.

The interesting point in these cases was the pathological nerve changes which caused the paralysis.

Dr. Cocks believed the cause to be a neuritis, and that usually they would recover, even without treatment; strychnine was his favorite remedy. Disease seldom lasted longer than two weeks.

[1] Obstet. Trans., vol. viii., Lond.

Dr. H. J. Wolf read the paper of the evening, entitled

TONSILLITIS LEPTOTHRASIS BENIGNA.

Dr. Richard reported a case of extensive laceration of scrotum, removal of lacerated portions, suture and immediate union. Also three cases of sciatica, in which he had tried all the new analgesics, but without success.—K. B. P.

ACADEMY OF MEDICINE.

SECTION IN OPHTHALMOLOGY.

October 21, 1889.

Dr. Pomeroy in the Chair.

Demonstration of a Case of Cataract Extraction, Dr. Herman Knapp.

Case of Microtesia; Opening of the Auditory Meatus, with Improvement of Hearing, Oren D. Pomeroy,

Case of Coloboma of the Choroid. per Weeks; Demonstration of the Use of Schweiger's Perimeter, Herman Knapp. —K. B. P.

POLYCLINIC THERAPEUTICAL SOCIETY.

At the last meeting of the Polyclinic Medical Society a therapeutical section was formed from among the faculty, clinical assistants and students of the Philadelphia Polyclinic, the object of which shall be the scientific and systematic investigation of the action of drugs and remedies in the cure of disease. The executive committee of this section formulates a programme of practical work for each meeting, decides what agents are to be investigated, devises specific directions in regard to such investigations, and supplies printed blank forms to carry the work into practical effect, with which any member of the profession who desires to take part in the research will be furnished free on application. These blank forms are filled out by the observers and returned so soon as the investigation is completed, which will be at the end of one, two or three months; at which time the reports will be analyzed and presented at the following meeting with due credit to each contributor, and the results will be published in the medical journals. It is believed that a combined effort of this kind will not only benefit those who are engaged in the work, but will be of great value to practical therapeutics.

Dr. Mays read a paper on

OLIVE OIL IN GALL-STONES

and olive oil in this affection was made a subject for investigation during the next two months. All communications in reference to the subject should be addressed to Therapeutical Section, Philadelphia Polyclinic.

Eight cases and two deaths from typhoid fever have occurred at Yale College within the past week, but the authorities deny sensational stories of a threatened epidemic, and state that the infection was in every case contracted previous to the arrival of the patient at the college.

Book Reviews.

TRANSACTIONS OF THE LOUISIANA STATE MEDICAL SOCIETY, at its Eleventh Annual Session, held at New Orleans, La., April 9, 10, 11, 1889. Pp. 364. L. Graham & Son, New Orleans, 1889.

The Louisiana State Medical Society enrolls a membership of 192, and, judging from these Transactions, is quite an active organization. The majority of the papers read are short, pithy, and practical; they are more numerous than is generally the case. After the various reports of committees and chairmen of sections comes the President's address, an able appeal for stronger organization and increased interest, by Dr. I. J. Newton. The annual oration, delivered by the Rev. T. R. Markham, is a highly literary and scholarly production, detailing the history of medicine and lauding it for its noble work in the general cause of humanity. In the various papers and communications read by the members, ophthalmology, surgery, gynæcology, therapeutics and general medicine are fairly well represented. Dr. R. Matas' paper, upon a multiple, subperiosteal sarcoma of the skull, is accompanied by a clearly-executed photogravure which adds much to its value. Puerperal eclampsia, by Dr. R. H. Day; The Surgeon of the Present Day, by Dr. F. Formento; and Circular Enterorrhaphy, by Dr. R. Matas, are among the most notable contributions deserving of special mention. The entire volume is full of interesting and instructive matter, and is worthy of something better than a mere paper back cover.

ELECTRICIAN'S POCKET COMPANION. By ANDREW JAMIESON, C.E., F.R.S.E. 12mo. Cloth, pp.64. New York: The Industrial Publication Company, 9 Barclay Street. Price, 75 cents.

This little book is invaluable to the practical electrician, and to the physician who desires, as he should, to understand the methods of testing his batteries, and of working out the formulæ involved in resistances, both of apparatus and patient. It covers every branch which the practitioner will need directions concerning, and it will give him an insight into practical electrical work which must be of great service to him. The illustrations are good, and sufficiently numerous to elucidate the points discussed in the book.

Pamphlets.

Antiseptic Obstetrics. By Charles Warrington Earle, M.D., Chicago. Reprint from the Transactions of the Thirty-seventh Annual Meeting, Illinois State Medical Association. 12 pages.

A brief resumé of the rise of antiseptic obstetrics, with rules and directions for physicians in their private practice, in order that the low mortality-rate of hospital practice may be more closely approximated.

Atropine in Enuresis. By William Perry Watson, A. M., M. D., Jersey City, N. J. Paper read before the Section on Diseases of Children, American Medical Association, Newport, R. I., 1889. Reprint from the *Archives of Pediatrics*, October, 1889.

The Medical Digest.

EAU DE COLOGNE.—The following formula was awarded the palm by the *Chemist and Druggist* out of 219 competitors:

Oil of bergamot	℥ij
" lemon	℥j
" neroli	gtt. xx
" origanum	gtt. vj
" rosemary	gtt. xx
Alcohol, triple distilled	Oj
Orange flower water	℥j

British weights and measures.

ANTISEPTIC SPONGES—Prof. J. Perrens.—Take a string of fine new sponges, neither too small nor too large. Commence by beating them with a small hammer, or a piece of wood, in order to knock out the dust and any mineral particles that they may contain. Examine particularly the point where the sponge was attached to the rock; often there are minute grains of sand firmly adherent at this point, and which should be absolutely removed to avoid irritating an already painful wound. It is better to cut this point off with the scissors. Having done this, wash the sponges freely in water, squeeze, and place them in fountain basins, preferably enameled ones, containing the following solutions:

1.	Hydrochloric acid	10 grammes.
	Water	1 litre.

Allow them to remain six hours in this mixture, then wash freely again in water, and steep them for six hours in the following:

Water	1 litre.
Permanganate of potash	1 gramme.

By treatment with chameleon solution of a beautiful, intense violet hue, they will become more or less rapidly discolored; and after washing freely in water, will retain a brownish shade.

Immerse the sponges next in the following liquid for two hours:

Liquid bisulphate of soda	10 grammes.
Water	1 litre.
Hydrochloric acid	1 gramme.

A slight odor of sulphurous acid gas will be perceived. After a little while the sponges lose their brown color, and assume a beautiful whitish yellow shade.

Wash again freely in water, and introduce them into a preserving fluid made as follows, where they should be kept until needed:

Water	1 litre..
Carbolic acid	1 gramme.
Alcohol	5 grammes.

Dissolve the carbolic acid in the alcohol and mix together the aqueous solution.

In order to remove the odor ot the carbolic acid, which the laity always associates with hospitals, we may use in place of the above solution the following preserving fluid:

Thymol	1 gramme.
Alcohol	4 grammes.
Water	1 litre.

—*Gaz. de Gynec.*

CASTOR OIL CHOCOLATE.—Giraud proposes to facilitate the administration of castor oil by incorporating it with cacoa. For this purpose he takes finely powdered cacoa, deprived of oil, such as it is found in commerce. With this he incorporates the castor oil, and adds a sufficient quantity of vanilla to flavor it. Next he adds sugar, and grinds the whole upon a heated slab. Finally he transfers the mass into moulds, and allows it to become cold.

He recommends the following proportions :

Cacoa, free from oil and powder.	50 parts.
Sugar, in powder	100 "
Castor oil	50 "
Vanilla, in powder	q.s.

[The size of the moulds may be chosen so that it will require from three to six of these "chocolate drops" to form a dose for an infant.]—*Am. Druggist.*

AFTER having reported two cases of anthrax in which carbolic injections had given most favorable results, Drs. Renoyan and Laride drew the following conclusions :

1. Subcutaneous injection of carbolic acid is an efficacious method of treatment for malignant anthrax, accompanied with grave symptoms.

2. In urgent cases these injections may be made with a ten per cent. solution (equal parts of neutral glycerine and water) and the dose of the injection may with safety in the adult be used as high as fifty centigrammes. In all other cases it is better to employ a five per cent. solution on account of the pain that is produced.

3. Under the influence of these hypodermatic injections, the general symptoms rapidly improve and the prognosis alters within 48 hours. The local condition is also favorably influenced.—*Revue Médicale.*

ELECTROLYSIS IN SURGERY.—The remarkable advances which have been made within the last decade and a half in our knowledge of electricity, and of its application to scientific purposes, are too well known to require further mention here. Dr. Robert Newman, of New York, however, in an admirable paper read before the meeting of the Ontario Medical Association in Toronto, on the sixth day of June last, has thoroughly reviewed the subject of electrolysis as applied to surgery. In the course of his paper he remarks that "the art in applying electrolysis successfully in surgery consists in :

1. Using the correct strength of the electric current.

2. Applying the respective poles in the right place.

3. Selecting the size, shape and material of the electrode.

4. Regulating the *duration* and intervals of seances.

He goes on to state that for the purpose of electrolysis a galvanic current only can be used, and that the negative pole should be selected for the immediate destruction of tumors and strictures, its action more closely approximating that of a caustic alkali, and leaving a cicatrix which is soft and not retractile.

His paper concludes with a review of the practical uses to which electrolysis has been put in the different branches of surgery. Aneurism, varicocele, hernia, hydrocele, hemorrhoids, tumors of various kinds, malignant and benignant, goitre, enlargement of glands, strictures of the œsophagus, rectum and urethra, atresia vaginæ, opacities of the cornea, extra-uterine pregnancy, endometritis, and the various uterine displacements are but a few of the many affections which he mentions as having been successfully treated by electricity.—*Canadian Practitioner.*

DIAGNOSIS OF CEREBRO-SPINAL MENINGITIS BY PUNCTURE OF THE LIVER.—Dr. C. Bozzolo reports in *La Riforma Medica* an interesting case of cerebro-spinal meningitis, in which the diagnosis was assisted by bacteriological observations made on the fluid obtained by puncturing the liver. A man aged forty-four, who had been ill for five days previously, was admitted into the clinic at Turin, suffering from feverishness, pain in the right side of the neck, jaundice, enlargement of the spleen, painful enlargement of the liver, bronchitis, and albuminuria. A rigor occurred more than once. Except the pain in the neck and vomiting, no symptom whatever of meningitis existed. Six days after admission the patient died, having been slightly delirious for the previous forty-eight hours. Diagnosis being difficult, the author had on the fourth day after admission made an exploratory puncture of the liver, which was still painful. The blood extracted showed by cultivation and after experiments on animals the existence in it of Fraenkel's diplococcus of pneumonia. This result, in the absence of pneumonia and pleuritic symptoms, with the existing pains in the neck and vomiting, encouraged Bozzolo to diagnose meningitis, a diagnosis which was confirmed by the post-mortem examination. In addition to the morbid changes in the meninges, gall-stones and acute endocarditis were found.—*Lancet.*

ANTIPYRETICS.—Surgeon Major A. Crombie, M.D., of the General Hospital, Calcutta, writing upon the comparative value of antipyrin, antifebrin and phenacetin as antipyretics, deduces the following conclusions :

1. As regards efficacy, antipyrin comes first, and there is little to choose between antifebrin and phenacetin when administered in the usual doses.

2. That as regards safety the advantage lies with phenacetin. I have seen a subnormal temperature as the result of the use of antifebrin, but never collapse, which I have once seen from the use of antipyrin.

3. As regards rapidity of action antipyrin, probably on account of its solubility, comes first, antifebrin second, phenacetin third.

4. As regards duration of effect, the advantage lies with phenacetin.

5. As regards certainty of action, I would quote them in the same order as that of rapidity—antipyrin, antifebrin, phenacetin.

6. As regards inconveniences, in this climate (India), phenacetin is followed by just as profuse sweating as either antifebrin or antipyrin, and this, to my mind, is the great drawback in the use of antipyretics.

—*The Indian Medical Gazette.*

Medical News and Miscellany.

BLOCKLEY is overrun with rats.

ERIE, Pa., has a diphtheria scare.

DR. J. W. WEST has removed to 1125 Wallace st.

DR. JOHN AULDE has removed to 1910 Arch street.

YELLOW fever is epidemic in various parts of Brazil.

DIPHTHERIA is epidemic at Gladstone, Henderson county, Ill.

ANOTHER sporadic case of yellow fever is reported at Key West, Fla.

THE Twenty-second Ward has an epidemic of colic among the horses.

A RESIDENT of Allentown, Pa., lost five children by diphtheria in two weeks.

THERE is an alarming spread of diphtheria and scarlet fever in Lawrence, Mass.

DR. CHARLES P. NOBLE has succeeded Dr. Kelly in the Kensington Hospital for Women.

THE hand of disease has its grip upon the royal heads of nearly every country in Europe.

COUNCILS Committee on Charities and Correction lately made an official inspection of the Almshouse.

A CHILD of eleven years died of meningitis, caused by a beating on the head, administered by her schoolmates.

THIS is a season of epidemics—diphtheria, typhoid fever, the World's Fair question, and co-education agitate the public weal.

THE Health Board of Fishkill, N. Y., with the aid of the police, took a diphtheria patient out of the hands of the faith-curists.

A WHOLE family on Pine street were prostrated from the effects of inhaling sewer gas which escaped from a broken pipe in the cellar.

DR. WILLIAM A. ROBERTSON, brother of Henry W. Robertson, Assistant Clerk of Select Council, died at his home in St. Landry Parish, La.

THE village of McSherrystown, Pa., is stricken with diphtheria. Many deaths have occurred. Hon. F. G. Sneeringer's family is among the most sorely afflicted.

THE Department of Agriculture is advised of three more cases of pleuro-pneumonia discovered among cattle landed at Deptford, London, from New York and Boston.

The physicians of St. Mary's Hospital were recently busy for over an hour sewing up wounds in the hands and face of a little three-year old child who had been bitten and mangled by a pet dog.

IN digging for the foundations of the Keystone Battery Armory, the remains of half a hundred paupers were unearthed. The spot was formerly a Potter's field.

DR. HENRY W. RIHL was tendered a banquet by the members of the Northern Medical Association at the Colonnade Hotel, October 9.

REPRESENTATIVES of an English syndicate are endeavoring to secure control of the Patent Medicine business in this country. We hope they will—and then fail.

BOGUS doctors are plentiful at present. One, a colored man, is under arrest at Trenton for causing a child's death, and two, at Lancaster, fled, just in time to escape prosecution.

THE American Academy of Medicine will hold its next annual meeting at Leland's Hotel, Chicago, Ill., on Wednesday and Thursday, November 13 and 14, 1889. Richard J. Dunglison, Secretary.

AN entertainment was given at Textile Hall, Kensington avenue and Cumberland street, in aid of the building fund of St. Christopher's Hospital for Children. A large audience was present.

A HALLOWEEN reception was given the students of the Medico-Chiruegical College on October 31, by Dr. A. S. Gerhard, of the Faculty, at his residence, Sixteenth street above Mount Vernon.

ONE of the finest and most fashionable localities in Paris is stricken with typhoid fever. The death rate from this cause is attributed to the proximity of numerous barracks and military institutions.

A RECEPTION was given to Professor W. W. Keen at the Bellevue, on October 26. Many of his friends were present. Dr. Keen has quite recovered from his recent illness, and is filling his lecture hours.

A SUIT has been brought against the city by a young man who was sent to the Municipal Hospital as a small-pox patient, when in reality he suffered with measles. Being subjected to infection, he contracted small-pox, which ruined his health and crippled him for life.

THE Americnn Association for the Study and Care of Inebriety has tendered a dinner to its venerable president, Dr. Joseph Parrish, in honor of the seventy-first anniversary of his birth. The dinner will be given in Burlington, N. J., Tuesday, November 12, at noon.

DR. E. G. MARTIN, Secretary of the Board of Trustees of the Norristown Insane Asylum, whose name has been mentioned in connection with the presidency of the Board, made vacant by the death of General Hartranft, says he is not a candidate for the position.

THE annual meeting of the contributors of the Maternity Hospital, at 734 South Tenth street, was held October 22, T. Morris Perot presiding. The annual report of the Board of Governors showed that during the year ending September 30, 111 women were received at the institution. Only one death occurred. Dr. L. G. Robinovitch was elected resident physician and Miss Mary Molder, matron. The Board of Governors earnestly appeal for aid to carry on their work.

THE estate of Rachel L. Bodley, late dean of the Woman's Medical College, was settled by Judge Penrose, of the Orphans' Court. By her will she bequeathed her scientific books and herbarium of dried plants to the Woman's Medical College of Pennsylvania, and the remainder of her books and cases to the Presbyterian Home for Widows and Single Women.

PROF. J. J. REESE, of the University of Pennsylvania, has sent a communication to the Board of Health, suggesting the passage of an ordinance prohibiting the embalming of bodies without a permit from the Board of Health. Bearing upon this, attention is called to the fact that the poisonous nature of embalming fluids would, in cases of suspected poisoning, cause serious trouble, or, perhaps, defeat the ends of justice.

To Contributors and Correspondents.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the co lumns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, United States Army, from October 20, 1889, to November 2, 1889.

By direction of the Secretary of War, so much of Par. 2, S. O. 241, October 16, 1889, from this office, as relates to Lieutenant-Colonel Anthony Heger, Surgeon, is amended to read as follows:

HEGER, ANTHONY, Lieut.-Colonel and Surgeon, is relieved from further duty in the Division of the Atlantic, and will at once report to the Major General commanding the Army for duty in this city. Par. 5. S. O. 252, Hdqrs. of the Army, A. G. O., October 29, 1889.

By direction of the Secretary of War, Par. 3, S. O. 241, October 16, 1889, from this office, is so amended as to grant Major Robert M. O'Reilly, Surgeon, leave of absence for six months, with permission to leave the United States, to take effect November 1, 1889. Par. 6, S. O. 252, A. G. O., Washington, D. C., October 29, 1889.

GIBSON, JOSEPH R., Major and Surgeon. Granted leave of absence for seven days, to take effect from date of being relieved from duty at Fort Sheridan, Ills. Par. 9, S. O. 249, A. G. O, October 25, 1889.

TAYLOR, THORNE K., Major and Surgeon (retired). Died October 20. 1889, at San Antonio, Texas.

War Department, Washington, October 30, 1889. By direction of the President, Major William H. Forwood, Surgeon, is detailed as a member of the Army Retiring Board at St. Paul, Minn., convened by W. D. order dated January 12, 1889, published in S. O. No. 10, January 12, from Headquarters of the Army, *vice* Captain Edgar A. Mearns, assistant-surgeon, hereby relieved. Par. 12, S. O. 254, A. G. O., October 31, 1889.

By direction of the Secretary of War, Captain William C. Gorgas, Assistant-Surgeon, is relieved from temporary field duty in the Department of the Missouri, and will join his proper station (Fort Barrancas, Fla.) Par. 2, S. O. 251, A. G. O., October 28, 1889.

By direction of the Secretary of War, so much of par. 10, S. O. 242, October 17, A. G. O., as directs Captain Louis M. Maus, Assistant-Surgeon, to report in person for duty at Fort Stanton, New Mexico, to relieve Captain Marcus E. Taylor, Assistant-Surgeon, is revoked, and Captain Taylor will proceed to Boise Barracks, Idaho Ty., as directed in said order, as soon as medical attendance shall be provided for Fort Stanton. Par. 10, S. O. 249, A. G. O., October 25, 1889.

MAUS, LOUIS M., Captain and Assistant-Surgeon. Granted leave of absence for two months, on surgeon's certificate of disability. Par. 11, S. O. 249, A. G. O., October 25, 1889.

So much of par. 2. Special Orders No. 241, October 16, 1889, from this office, as directs Captain Louis Brechemin, Assistant-Surgeon, to report for duty at Fort Apache, Arizona Ty., is revoked. He will report in person to the commanding officer, Presidio of San Francisco, Cal., for duty at that station. Par. 7, S. O. No. 248, A. G. O., October 24, 1889.

CHAPIN, ALONZO R., Captain and Assistant-Surgeon. Relieved from duty at Newport Barracks, Ky.,and will report in person to the commanding officer, Fort Yates, Dakota, for duty at that station. Par. 7, S. O. No. 248, A. G. O., October 24, 1889.

SHANNON, WILLIAM C., Captain and Assistant-Surgeon. Relieved from duty at Fort Yates, Dakota, and will report in person to the commanding officer, Fort Apache, Arizona Ty., for duty at that station. Par. 7, S. O. No. 248, A. G. O, October 17, 1889.

DAVIS, WILLIAM B., Captain and Assistant-Surgeon Relieved from further duty at Fort Porter, N. Y., and will report in person, upon expiration of his present sick-leave of absence, to the commanding officer, Fort Preble, Maine, for duty. Par. 6, S. O. No. 248, A. G. O., October 24, 1889.

WAKEMAN, WILLIAM J., Captain and Assistant-Surgeon. Relieved from duty at Fort Walla Walla, Wash. Ty., and will report in person to the commanding officer, Fort Bidwell, Cal., for duty at that station. Par. 7, S. O. No. 248, A. G. O., October 24. 1889.

EGAN, PETER R., Captain and Assistant-Surgeon. On being relieved from duty at Camp Eagle Pass, Texas, will report in person to the commanding officer, Fort McIntosh, Texas, for duty at that station. Par. 7, S. O. No. 248, A. G. O., October 24, 1889.

MEARNS, EDGAR A., Captain and Assistant - Surgeon. Granted leave of absence for two months. Par. 5, S. O. No. 244, A. G. O., Oct. 19, 1889.

CABELL, JULIAN M, First Lieutenant and Assistant-Surgeon. Granted leave of absence for two months, to take effect about Nov. 10. Par 7, S. O. 249, A. G. O., October 25, 1889.

CLENDENIN, PAUL, First Lieutenant and Assistant-Surgeon. Relieved from duty at Fort McIntosh. Texas, and will report in person to the commanding officer, Camp Eagle Pass, Tex., for duty at that station. Par. 7, S. O. No. 248, A. G. O., October 24, 1889.

RAYMOND, HENRY I., First Lieutenant and Assistant-Surgeon. Upon being relieved from duty at Fort Bidwell, California, will report in person to the commanding officer at Newport Barracks, Ky., for duty at that station. Par. 7, S. O. No. 248, A. G. O., October 24, 1889.

KENDALL, WILLIAM P., First Lieutenant and Assistant-Surgeon. Leave of absence extended one month. Par. 6, S. O. No. 244, A. G. O., October 19, 1889.

APPOINTMENTS:

WILLCOX, CHARLES, First Lieutenant and Assistant-Surgeon. To rank from October 29, 1889.

MCVAY, HARLAN E., First Lieutenant and Assistant-Surgeon. To rank from October 29, 1889.

FRICK, E. B., First Lieutenant and Assistant-Surgeon. To rank from October 29, 1889.

By direction of the President, the Army Retiring Board convened at Vancouver Barracks, W. T., by War Department order dated December 15, 1888, published in S. O. No. 292, December 15, 1888, from Headquarters of the army, is dissolved. Par. 1. S. O. 250, A. G. O., Washington, October 26, 1889.

Changes in the Medical Corps of the United States Navy for the week ending November 2, 1889.

NASH, F. S., Passed Assistant-Surgeon. Detached from duty in Bur. Med. and Surg., and to the Petrel. November 14, 1889.

BOGERT, E. S., Medical Inspector. Ordered to examination preliminary to promotion to Medical Director.

Assistant-Surgeons O. D. Norton, I. W. Kite, and E. P. Stone. Ordered to examination preliminary to promotion to Passed Assistant Surgeons.

Medical Index.
